NEW YORK

# COAL AGE

With Which is Consolidated  
The Colliery Engineer

## INDEX TO VOLUME XXVI

July 1 to December 31, 1924

NOTE—The articles and references in this index have been classified under leading subjects or topics, as far as practicable, and should be sought under such heads, which together with all unclassified matter are arranged alphabetically. Illustrated articles or cuts standing by themselves are indicated by an asterisk (\*). All editorials appear under that subject, each having its exact title. Elsewhere the subject matter of an editorial will be found classified and marked (e). Many titles of articles are abbreviated, the aim being to give prominence to important words.

Following is a list of the pages included in each issue of the volume, together with date and number of the issue, for convenience of reference:

	No	Pp.
July	3	1-34
"	10	35-68
"	17	69-106
"	24	107-138
"	31	139-174
Aug.	7	175-208
"	14	209-244
"	21	245-280
"	28	281-316
Sept.	4	317-352
"	11	353-388
"	18	389-424
"	25	425-460
Oct.	2	461-496
"	9	497-532
"	16	533-568
"	23	569-604
"	30	605-638
Nov.	6	639-674
"	13	675-708
"	20	709-742
"	27	743-780
Dec.	4	781-816
"	11	817-854
"	18	855-890
"	25	891-926

### A

	Page
Accidents. See also "Fatalities"	
—Falls and other causes; tables	12
—Old men more subject to accident	22
—Reporting mine accidents (e)	36
—Fatalities for May, classified; table	53
—Prevention work spreads in Penna.	53
—Coal-mine accidents, U. S.	192
—Haulage accidents rank second to roof falls	225
—Fire in Lincoln mine, Ohio	300
—Air blasts from falling roof kill miners	326
—Johnstown (Pa.) flood, 1889, survivor	*338
—Disasters, 1910-1924 due to electricity; table	434
—Care in choice and keep of fuse and switches	*468
—Precautions to avoid accidents	471
—Coal mining vs. other industries (e)	497
—Frequency and severity rates in industries; tables, 513; Causes of temporary injury; table	514
—By causes and states, Aug., 1924; table	519
—Mine-haulage accidents far too frequent	557
—Clock showing lost-time accidents	585
—Few mine accidents under Pinchot régime	622
—Bumps cause accidents in Johnson colliery	*641
—September report, Bureau of Mines	659
—Three accidents in starting locomotives	*663
—Miner loses two thumbs from one hand	838
—Fatal cave-in, Springfield mine, N. S.	841
—More numerous in morning; roof hazard greater	844
—Few accidents in Mexican mines	894
—Nunnery mine accident, Sheffield, Eng.	905
—Boy burned by powder found in mine	912
—Addy Co. may reorganize, Cincinnati	372
—Aerial tramway solves rock disposal problem	*363
—Air blasts from falling roof kill miners	326
—Air condition as to temperature and moisture (e)	389
—Air-lift and Japan mines interest anthracite engineers	799

### Alabama

—Mobile Chamber of Com. protests coke rates	351
—Output and value of coal 1923; table	410
—Coal seams, output, analyses, etc.	*473;
—Typical section	*540
—Production, Warrior, Plateau and Coosa fields, table, 475; Cahaba field, table and map, 476, *539, 797; Geologic sections, 477; Analyses and fusing temp's of ash, table	478

### Alabama—Continued

—Coal-washing and cleaning practice makes good coke	*501
—Progress in coking coal	*506
—Coal-mining methods vary widely	*509
—Details of mining the coal beds, *537; Output per man, per day; table	540
—Equipment and safety methods	*577
—Blast furnace, Tenn. C. I. & R.R. Co., Ensley	*587
—Birmingham, Plan better handling of coal	637
—Jacksonville agreement setback to union fields	729
—Marvel plant largest in Cahaba field, *796; Alabama coal fields and map	*797

### Alaska

—Bureau of Mines studying Alaskan coal	402
—Matanuska coal field, 7,000 tons monthly; Geol. Survey completed	896

### Analyses

—Ash analyses in cleaning coal; table	219
—Coal, Deep River field, N. C.; table	394
—Water, type of analysis depends on use	399
—Flotation test, ash content; table	503
—Bayview mine (Ala.) washery tests; table	504
—Animals in mines cause infection	46

### Anthracite

—Wages rise faster than other industries	158
—Operators to teach public heating by small sizes	191
—Operators violating the law, no evidence of	193
—Circular prices for August anthracite; table	232
—Pulverized anthracite slush burned in power plant	*253
—Mines shut down awaiting orders and cars	263
—Production by breakers, washeries and dredges; table	265
—Big merger of independents planned	298
—Safety inspector urged for each colliery	337
—New Temple Anthracite Coal Co. formed by merger	371
—Circular prices for Sept.	373
—Canada seeks substitute for U. S. anthracite	374
—Shipments, 1923, tonnage and value; table	376
—Sproul interests effect new anthracite merger	411
—Colonial Colliery Co. absorbs Madeira Natalie and Greenough operations	443
—Circular prices for October	480
—Mines flooded by rain storm	517
—Two mine fires within few days	554
—U. S. operators visit European mines	623
—Six coal firms to consolidate	624
—Outlaw strike of anthracite miners	626
—Analysis of coal, Dunmore No. 3 bed; table	643
—Sproul consolidation about complete	662
—Semi-coke to supplement anthracite	687
—Inspection tour of magnates deepens interest in merger	694
—Storage plant, Hudson Coal Co., Jermyn, Pa.	*813
—Circular prices for December	839
—Supreme Court holds tax constitutional	840
—Seek greater mine safety	876
—Economy service traveling show	*887
—Miners want coal tax repealed	914
—Strike end expected	914
—Warriner resigns from Conciliation Board	914
—Appraisal organization aids all property	328

### Arkansas

—Output and value of coal, 1923; table	410
—Coal-mine statistics, 1923	876

### Associations

—Am. Assn. of Engrs. pledge aid to President	374
—Am. Chem. Socy., Fall convention, Ithaca, N. Y., 121; To discuss coal storage	263
—Am. Eng. Council urges coal storage	52
—Am. Inst. Mg. & Met. Engrs.: Arrange program for Birmingham meeting, 20; Visit southland; Tour and banquet, *582; Visit Illinois coal mines	662
—Am. Mg. Congress: Standardization conference, 411; Discusses coal situation, 547; Names tax committee	727
—Big Sandy Coal Assn., N. E. Ky., combats discrimination	626
—Bit. Coal Operators Assn. asks readjustment of union contract	692
—Brotherhood Investment Co., W. Va.	54
—Central Penn. Bit. Coal Operators and Producers Assn's. joint meeting to boost output	371
—Civil Liberties Union, move to protect miners	299

### Associations—Continued

—Coal Mg. Inst. of America: Pittsburgh meeting planned, 552; Balloting for officers, 624; Advance program, (e) 676; Holds post-graduate course, (e) 743; Discussions at Pittsburgh meeting	*819
—Colo. and N. Mex. Coal Operators Assn. asks revised coal rates	315
—Eng's Club of Scranton, discussions	799
—Eng's Socy. of Western Penn. discuss rock dusting	799
—Federal Trade Com. report on dock charges	517
—Illinois Mg. Inst., 3-day cruise on Mississippi	*19
—Joseph A. Holmes Safety Assn., 45; Grows rapidly	864
—Monongahela Coal Assn. seeks cut in Baltimore scale	122
—Nat'l. Coal Assn.: Appoints com. to reduce waste, 160; Forms research com., 451; Urges use of soft coal, 554; Authorizes research program, 588; Will strive to bring public and operators closer together, 589; Names com. to U. S. Chamber of Com., 592; Cost accounting and tax com. named, 626; Discontinues "Coal Review," 875; (e)	891
—Natl. Elec. Light Assn., Report of Prime Movers Com.	686
—Natl. Industrial Conference Bd. sees end of slump	230
—Nat'l. Minrs. Assn. decries quick remedies; Officers elected	912
—Natl. Purchasing Agents Assn. estimate coal supply in storage, 442; Report stocks increase	624
—Natl. Safety Council: Calls meeting at St. Louis, 42; Annual meeting; tentative program, 300; Completed program, 339; Opening session, 482; Full report of congress	*513
—New York State Coal Merchants Assn. hold big convention	376
—Northwest Coal-Dock Operators Assn. unfair methods	517
—Pittsburgh Coal Producers Assn. want rates cut	300
—Pittsburgh mining institute may be formed	765
—Proposed coal institute regarded unfavorably	552
—Royal Com. on Mining Subsidence, 508, 557	
—Rocky Mt. Coal Mg. Inst., Rock Springs meeting	227, 258; 289
—So. Wales Inst. of Engrs. discuss bituloid	691
—Trade assn's: Officials confer on status; 443; Hoover silent, 517; Assn's. to study uniform cost accounting, 592; Ruling asked on activities	803
—W. Va. Coal Mg. Inst. meeting, 835; Photo, *875; Gary trip	*877
—W. Va. Ky. Assn., Eng's. plan program, 802; Discuss problems and experiences	907

### Austria

—Coal output gains	21
--------------------	----

### B

—"Bacon and beans"	159
—Banker vs. promoter, Narrowing gulf between	327
—Baum jig and washer	*177
—Bearing with rollers tapered to meet thrust	*387

### Belgium

—Campine region coal field discovered	*247
—Campine mining villages like garden cities	*283
—Winterslag improvements	*284
—Coal miners strike against wage cut	300
—Benzol, British govt. to study	370

### Bids

—Navy Dept. asks bids at So. Brooklyn, 300; Keen competition	337
—N. Y. City Dept. many bids, wide range	589
—New Haven R.R. seeks bids, 695,839; Opens bids	878
—"Bituloid" as dust layer, British experiment, 615; Discussed at Cardiff	691
—Black powder, See "Explosives"	
—Black Servant Coal Co's. (Ill.), strip pit, *319	
Blasting. See also "Explosives"	
—Drilling shotholes in coal face	*38
—Short fuses: Inserting detonator;	161
—Storage; etc.	
—Should air space be used with black powder?	164
—Misfire may be caused by uncleaned shothole	267

	Page		Page		Page
Blasting—Continued		Canada—Continued		Need of trade assn's.	14
—British make near safety rules	447	—Coal deposits not central, (e)	710	—Coal industry progressive, (e)	317
—Square dealing in company shooting, (e)	461	—August coal output lowest of year	728	—History of American mining lacking, (e)	318
—Drilling shot holes, *574; Loading a hole,	*575	—Nova Scotia bumps due to pressure	750	—Banker vs. promoter, Narrowing gulf between; Financing mining proposition	327
—Dangers in elec. blasting, *574; Rules in blasting, 575; Strength of safe current	576	—Nova Scotia miners to demand higher wages	804	—Car shortage may catch tardy coal buyers	336
—Vertical shearing saves powder	*607	—Springfield mine, N. S., fatal cave-in	841	—American methods efficient, (e)	353
—Coal face shot down, *609; powder per ton of coal; table	609	—Miners vote to form own union	841	—Shop equipment past and present, (e)	354
—Britain revises shoring rules	646	—Spread of central heating system foreseen	875	—Irregularity originates in other industries, (e)	354
<b>Boilers, and Furnaces</b>		—September coal output	876	—Coal barons have no primrose path	374
—Resurfacing seats of tube-hole covers	*194	—New wage contract and miners' assn.	876	—Nation using less coal finding price too high	396
—Anneal boiler tubes before roll them	195	<b>Cars</b>		—Coal comp'y raises milk, as side line	*396
—Cross-section of boiler and furnace, Lykens, Pa.	*254	—Wheel with double tread	*68	—"The Coal Industry," Shurick	414
—Six boilers served by one stack	257	—Swivel mine-car hitching should be lubricated	*149	—Indiana move to patronize house industry	482
—Stoker for small boilers	*280	—Builds 2-ton mine car in 5 hr.	154	—Accident record vs. other industries, (e)	497
—Burning screenings smokelessly	*280	—Sprinkler car wets roof, ribs and floor	*267	—Needs to be let alone, (e)	534
—Device to keep water at fixed level	*315	—Car designed for safe transport of hay	*292	—Publicity as a business policy, (e)	569
—Bentube evaporators prevent scale and keep clean	*315	—Saving time in gathering mine cars	*306	—Low-priced fuel marks industrial advance	570
—Hopper-feed hand stoker, many advantages	*386	—Dump car operated by steam from locomotive	*351	—Soft coal vs. fuel oil	588
—Scale harmful, 399; Cost of scale accumulation *400; Effect of dif. impurities in feed water and remedies; table	402	—Rock-dusting car, Springdale mine	*411	—Coolidge decries federal control	590
—Seek better refractories for furnace lining	438	—Logans Ferry, Pa.	*557	—Learning facts in other industries, (e)	639
—Turbo-undergrate blower	*460	—White coal car, U. S. Fuel Co., Salt Lake City, U.	*573	—Need of greater publicity, (e)	676
—Powdered-coal furnace no longer an experiment; Yearly increase in area of heating surface; diagram	*720	—Mine car built in less than 3½ hr.	*714	—Many fields, Trent process opens	716
—Typical powdered-coal fired boiler	*721	—Specially designed car for rock, clay, etc.	*844	—Soft-coal industry benefits consumers," Coolidge	726
—Boiler economies for coal men exhibit at power show	864	Carnegie Inst. to train graduates at mines	832	—Central Pa. mines show new life	728
<b>Book Notices</b>		Castlegate mine disaster, Recovery work	323	—Weak market condition met by big equipment	*751
—Practical Calculus for Home Study; Palmer	13	Canca Valley coal convenient to Panama	798	—Is industry blind to health hazards in mines	*757
—"CoalDEX," Pamphlet, H. E. Friend	183	<b>Cement</b>		—Seeks to curb opening new mines	800
—Resistance of Entry to Air, Bureau of Mines	286	—Cement mortar prevents dust lodgment	*785	—Warns against coal profiteers in New York	801
—"Pulverized Fuel," W. F. Goodrich	414	Cinderella miners build swimming pool	*362	—Brotherhood of Locomotive Engr's in coal business, (e)	818
—"The Coal Industry," A. T. Shurick	414	Clearfield Bituminous Coal Corp., Forestation	*124	—Child labor small, (e)	818
—"The Price of Coal," Shinwell, London	438	Closed door, The	*90	—Safer operation and cheaper coal	822
—"The Amer. Socy. Htg. and Ventg. Engrs. Guide, 1924	450	<b>Coal. See also "Production"</b>		—Effect of Jacksonville agreement	837
—"Byproduct Coking," Cooper and Myers	450	—Oil vs. coal, (e)	2	—Coal organization largest in years	839
—"Coal Review" discontinued	875; (e) 891	—Cure for "coal baronism"	16	—Stabilizing the industry, (e)	855
Breathing apparatus, See "Rescue Work, Mine"		—Imports at Rio de Janeiro, U. S. exceed British	19	—Need of accurate output figures	874
Briquets, See "Fuels"		—Consumption in coking	20, 122	—British industry prosperous in 1923	875
Buildings, See "Headframes and Tipples"; "Mining Towns and Housing"		—Output of Russia mines	21	—Hoover peace vs. Penn. mining	912
Bulletin board for mine yard	*358	—Dock shipments decline	21	<b>Coal Mining</b>	
Bumps and shocks working pillars, *641, 750		—Austrian output gains	21	—Better methods presaged by program to save timber	804
<b>Bureau of Mines</b>		—Heating value of coal burned, (e)	35	—Waste in the mining of coal, (e)	856
—Feehan, safety commr. indorses elec. cap lamps	56	—Competition with fuel oil, 50; Coal cheaper	51	—Twenty-four men load 289 tons daily	861
—Plans further co-operation with British	93	—Consuming public vs. coal operators, (e)	70	—Progress in underground transportation, (e)	891
—Testing gallery for electrical devices	*223	—Exports and imports decline	122	<b>Coal Storage</b>	
—Investigates stream pollution by mine waste	229	—Consumption by utilities	123	—Solution of nation's coal problem	52
—More speed in testing urged	232	—Freakish coals in Scotland	128	—Amer. Engr. Council com. study problem	433
—Investigation of mine resistance to air	286	—Selling fine coal	139	—Estimate 46-das. supply, Purchasing agents	442
—Study Washington and Alaskan coals	402	—Regulating "King Coal"	144	—Domestic storage aids industry, (e)	462
—Study washing of Freeport (Pa.) coals	430	—Hydrogenation of coal to obtain oil	156	—Screenings, Seasonal low price, (e)	497
—Elec. equipment approved, List of	434	—Low-grade lignites in Canada	156	—Only adds to congestion	547
—Seek better refractories for furnace linings	438	—Powdered coal efficient	156	—Banks to finance storage	591
—Engineer reaches mine disaster via air-mail service	483	—Storage of coal urged by Hammond	158	—Commercial stocks on hand increase	623
—Electrical equipment investigations, (e)	533	—"Mount Olive" coal ruling	160	—Engineers' report ready	764
—"Miners' circulars," (e)	781	—Waste in use of soft coal, To reduce	160	—Purchasing agents report more coal being stored	801
—Budget allowance lowered	839	—Statistical information needed in coal depression	190	—Anthracite storage plant, Hudson Coal Co., Jermyn, Pa.	*813
—Bain's annual report	877	—Consumption in power production drops	193	—Correcting previous storage figures	874
<b>California</b>		—Ratio volatile matter to total combustibles; table	197	<b>Coke and Coking</b>	
—Mining Congress, Sacramento convention	547	—Leadership in purchase of coal, (e)	209	—Byproduct and beehive output; Coal consumption	320, 122
<b>Canada</b>		—Business improving; Wootton	230	—More Connellsville plants return to 1917 scale	55
—Peace River (B. C.) coal almost equals W. Va.	18	—Utilities more efficient in use of coal	231	—Carnegie producer plant, Clairton, Pa., biggest	56
—Two provinces as coal supply limited	22	—Ocean carriers revert to use of coal	231	—Output coke, iron and steel low in June	122
—Vancouver coal fields hard to work and	120	—When coal is gone, what is to be done? West Va. smokeless coal brisk operation 6 mos.	252	—Farrell plant closes as new Clairton ovens open	298
—Low-grade lignites a problem	156	—Coal stock report to come	298	—Accident rate falls	322
—Alberta strike not settled	231	—Production on competitive basis needed	299	—Mobile Cham. of Com. (Ala.) protests coke rates	351
—Slump in coal output	232	—Five-ton block of coal as war memorial	300	—British govt. will study coke, benzol and gas mfr.	370
—Hudson's Bay Co. entered coal business in 1852	264	—Brown coals useful as fuel	329	—Coking coals, vary in structural strength	406
—Shock attack on U. S. coal delayed	265	—Lignite, Darco, a boneblack, new product of	334	—Salt damages walls of coke ovens	430
—Dominion Coal Co. plans equipment financing	336	—More coal statistics needed	335	—Coal and coke in house-heating plants	434
—Alberta Conciliation Bd. urges \$5 scale	338	—Consumption, 1923, Dept. of Com. report	337	—Byproduct coking, Book review	450
—Seeks substitute for U. S. anthracite	374	—Heating in storage, Conditions favorable to Engrs' com. report coal shortage unlikely	372	—Coking by steam, (e)	461
—Alberta miners again refuse 12½% cut	410	—Utility coal consumption hits bottom	375	—Coking strip-pit coal in Ill.	*485
—Alberta coal cannot go east	411	—Exports U. S. and Gt. Britain; table	375	—Screenings, Storage vs. coking, (e)	497
—Imports of British coal decline	440	—Analysis, 4-ft. seam, Deep River field, N. C.; table	394	—Alabama coal-washing and cleaning practice	*501
—U. S. coal shipments decline	481	—Consumption less, owing to high price	396	—Great progress in Alabama: Semet-Solvay byproduct ovens, Birmingham, Ala.	*506
—Alberta mines not likely to open, 520; Soon to open	620	—Origin and formation, Theories of	404	—Output, 1923, makes record	590
—Alberta, making briquets from coal dust formerly wasted	544	—Coking coals vary in structural strength	406	—Elec. light plants contemplate gas, coke, etc business, 686; Semi-coke to supplement anthracite	687
—Western Canadian miners accept wage cut	553	—Resources ample for many years, (e)	425	—Making coke from non-coking coals by froth flotation; Saar Valley coal, France	867
—Nova Scotia, Plan of mining coal fed	*558	—Keep cool with coal, (e)	426	—Connellsville independents to fire 2,500 ovens	911
—American markets vs. Canadian coal, (e)	569	—Tar yield of Western lignites	433	—"Colliery Engineer," The, (e)	354
—Govt. to aid coal shipments to central districts	591	—Analyses of Alabama coals; table	478	<b>Colorado</b>	
—Cassidy, B. C., Old works flushed with fine rock	*654	—Storage vs. coking of screenings, (e)	497	—Victor-Amer. Fuel Co., shake-up of officials	408
—Western miners work after close vote to end strike	661	—Consumption in various industries	590, 591, 624, 626	—Amer. Smeltg. & Ref. Co. lamp-rack, Boncarbo mine, *413; Rock-dusting machine	*429
		—Big chunk mined	*617	—Output and value of coal mines, 1923; table	445
		—Coal balls, "finger prints" that identify coal	*656	—Producers see good Fall prospects	444
		—"Back to coal" in oil heating plant	658	—Mine feud referred to Gov. Sweet	519
		—Campaign for clean coal; Ohio engr's report; Base-grade analysis sought	661	—Moffat tunnel through Rockies	*520
		—Bone-coal problems, (e)	710	—V-panel mining progressing in south	*711
		—Pulverized coal, Growth in use of	721		
		—Analysis of Lower Kittanning coal; Upper Freeport bed, 723; Pittsburgh bed	724

James H. McGraw, *President*  
E. J. Mehren, *Vice-President*

Devoted to the Operating, Technical and Business  
Problems of the Coal-Mining Industry

R. Dawson Hall  
*Engineering Editor*

Volume 26

NEW YORK, JULY 3, 1924

Number 1

## High Wages Promote Idleness

IF THE miner got a laborer's pay, he would be willing to accept a laborer's job, but partly because he gets from \$7.50 to \$9 a day the miner sticks to the industry and lies idle when the mines are closed. Lots of men will tell you a miner is as good as a "wood butcher" and therefore entitled to the carpenter's wages. Perhaps, but is the carpenter justified in getting his present pay? Furthermore most of the highly paid carpenters live in a city, have to pay city rents, have to travel long distances to their work and probably in the next few years they will be getting much less than today, for the era of construction has in most places already ended.

## Economy in Rockdusting

THOSE who are purposing to rockdust their mines should look over their mine cars with the intention of making them at least relatively dustproof. Only by keeping coal from falling on the tracks can the cost of rockdusting be kept at a minimum. Whether the roads are rockdusted or not—and who is not going to use rockdust?—it is well to keep the coal dust on the roads at the lowest possible quantity. Those who anticipate difficulty in keeping the required percentage of rock dust on the roads should remember that the sand deposited by the haulage locomotives and ground under the wheels will materially assist in complying with the regulations of the insurance companies. In fact the sand thus distributed has probably already had no little effect in limiting explosions.

## Will Gas Making at Mines Stabilize the Industry?

ACCORDING to the experts who reported on the Buffalo fuel problem, that city requires twenty-four million cubic feet of gas daily during the winter and an average of only about fifteen million cubic feet per day. Using the exact figures of the report the maximum demand averaged over a month would be one and two-thirds times the average for the year. Again comparing the maximum monthly with the minimum monthly demand the ratio would be two and two-thirds.

One cannot see that a demand so fluctuating would do much to correct the seasonal character of the coal industry if the plant were placed at the mine. The colliery that would supply such a line would work six days a week in the winter and two and a quarter in the summer. Not quite a pleasing prospect! The owner who would operate such a mine at full time would have to enter the general market and cut prices drastically.

To be perfectly frank, many of the much lauded industries function as badly or worse than the coal

industry. Authorities deny that fact, of course, and the public believes them, but facts are facts. The world is badly out of joint. The farmer and builder are idle in winter, the miner in summer. Some have two periods of idleness in the year and others have longer rests at greater intervals. But idle periods come to almost all workers, especially if they will not change their tasks. They come to their employers also who cannot change their equipment as readily as a man can change his job. It's just as well the public thinks the coal man is the only seasonal employer; if the public only knew the facts it would lose faith in humanity.

## Progress in Safety

IN THE article by N. G. Alford in this issue is much assurance for the future. He believes that the biggest hazard of the present will be reduced before long by mechanical loading, for roof falls are going to be controlled more effectually when greater speed of extraction is attained. Despite the fact that the cutters and loaders make more noise than hand picks and that the loaders will work on the goaf face instead of from a crosscut in the body of the pillar, he anticipates greater safety. That, of course, remains to be proved.

The conditions which have enabled Col. E. O'Toole to mine pillar coal more safely than room coal may not be universal. "Kettle bottoms" are not found in every mine. Mr. Alford ascribes the safety in pillar drawing in Col. O'Toole's mines to the fact that the kettle bottoms are loose over the pillar whereas in an advancing room they are so tight that they are not noticed. Suddenly in advancing places they lose their hold and fall, whereas in pillars they come down with the coal. A similar condition, however, is not unusual with ordinary drawslate. So perhaps he is right. The drawslate and kettle bottoms will no longer be a big hazard, and the roof proper or the thicker drawslates will not be a menace when the rapidity of extraction is increased.

Rockdusting will defend us against coal-dust explosions and if we can keep our cars coupled at the loading and discharge points we can save both casualty and time losses. Better cars and surer tracks with wheels kept from flattening and grooving will do much to minimize derailments. It is well if this can be done as greater speeds, more machinery and more gas are likely to add to our dangers. Let us hope we may overtake Great Britain in the loss of life per man employed as we have surpassed her per ton mined.

The present need is to keep in constant mind G. B. Butterfield's slogan, "Every mine rockdusted by Oct. 1." If this is to be done, we must be up and doing, for a mine that is operating cannot be properly dusted in a few days, and machinery for the work even if dust is purchased cannot be obtained with promptitude seeing that at present only one or possibly two firms are engaged in its manufacture. As the winter ap-

proaches with its ghastly forebodings, every effort should be made to obtain such machines and do such dusting. Let not another winter be approached with the mines unprepared.

### A Phenomenon or an Illusion?

WE DO not attempt to explain it. Some things are altogether above and beyond us. We cannot hope to tell anyone why coal mining is the "worst functioning industry." It is plainly a phenomenon, an inexplicable fact of nature. The British likewise find it hard to explain; it is puzzling the French. The Germans, who have solved every problem but the value of the mark, also find this problem difficult.

Arnold D. McNair, in a booklet on the British coal situation entitled "The Problem of the Coal Mines," says: "The reason for the frequent crises in the coal industry is the bad organization of that industry," and the next charge is "The principal defect in this organization is that it does not allow the miner to take a more active and more mental part in the industry." Clearly the industry is wrong because the employer and not the employee directs it. Mr. McNair having solved one phenomenon so easily, What is wrong with the coal industry?, let him try and solve the other one, "Why is the coal industry more wrong than any other industry?" There are other industries beside coal that are not directed by employees and in which employees take no part in direction. In fact there are few indeed and those small that are directed from the bench instead of the office. But in none of those cases has the industry been made wrong or worse functioning. Only coal should think it necessary to let brawn direct brains.

Most of the criticism of the coal industry is absolutely true and relatively false. Every essential industry in every clime unless regulated by the government to its minutest detail is sure to be said to function badly. When it is government owned, operated or controlled the public is satisfied through conditions may be worse. The public then is manager and cannot find fault with its own management unless it is glaringly and transparently inefficient and blundering. After all is said the coal industry is not the worst or the worst-functioning industry. It is not a phenomenon we are discussing; it is an illusion. But are not all illusions phenomena?

### Rockefeller Sheds No Tears

JOHN D. cracked his crude oil and made gasoline and a byproduct that he could not sell except as fuel oil. He could not dispose of enough of this byproduct. Still he wept no tears. He sent out his agents to tell how excellent a value the public was overlooking, that oil was better than coal any day, better for this and better for that. He wasn't weeping. He was merchandising.

The coal man weeps. He is worrying about no sale for slack and about the inroads of oil. Let him take after Rockefeller. Let him get all his facts together and sell slack. Maybe then the same jinx will get him that got John D. He sold so much oil that the price went up, and it doesn't pay to use fuel oil any more. He depressed the coal market so much with his oil that it paid the consumer to change his equipment and burn coal.

Get after him as he got after the coal man. Perhaps

his oil will come down from lack of sale and your fine coal will go up by reason of excessive demand, so that once more oil will have a day—a brief day—in the sun.

But shed no tears. It is active, concerted effort that will sell slack. No forebodings, fears, lamentations, prognostications, regrets, none of the many formularies we have been accustomed to use for the cure of the situation will help the sale a jot. Just plain merchandising of an idea and that idea that fine coal with mechanical stokers and medium sized coal on grates will do the work better than oil or coarser coal. Don't rest satisfied with putting a card in the local papers with your name and address and the name of the mine or region from which your coal comes. Try to sell an idea—the idea you want, the idea the consumer wants.

You couldn't convert the African to the value of ice by sending over a business directory. To get anywhere you would have to sell the idea of using ice to these gentlemen of color. It's the same with fine coal. The consumer knows what it is and doesn't want it, till he is told why he should want it, the labor it saves, the service it renders, the price it is sold for. Sell him individually and collectively the idea of the economical use of fine coal, and all the problems of merchandising and operation will be solved except that a crusher may soon have to be purchased at your mine.

### Arguments for Unionism

A FEW weeks back a coal operator obtained a contract from a railroad company by ruthlessly underbidding his competitors. The price he set for his coal was \$1.50 a ton. No sooner had he obtained the contract than he went down to the mines and notified his employees that the price for which he had sold his coal would not permit him to pay them the former rate of wages. They must accept a reduction of one-third in the wage scale. The employees accepted the wage cut and continued at work.

This kind of cut-throat competition is making operation difficult for companies who desire to use their men fairly and is reducing the wages of mine workers below the cost of even the most frugal living. No wonder that operators have at times advocated unionism arguing that such unfair competition was making the operating of coal mines an industry in which few well-meaning men would care to engage. Such behavior has convinced some operators and is fast convincing others that the beneficence of the employer is not a sufficient pledge that mine workers will receive honorable treatment. Not many men are disposed to conduct their business in that manner, of that we may be sure, but what of that? With a few men playing their hand so unfairly it becomes increasingly necessary for all their competitors to be equally callous as to the needs of their employees and to ask their men to consent to receive wages which their employer knows is below their needs and deserts and not in accord with the best business ethics.

Many times in the past has competition in the reduction of wages argued effectively for unionism and for its recognition by employers. Beware lest it argue again and so forcibly that the expression the "Solid South" will be applied to its unionism instead of its politics.

Interior of Boiler Room, Donk Mine No. 4

## Illinois Mine Generates Own Power Cheaply

All Pickings and Some Slack Burned—Superheated Steam Used—Exhaust from Hoist and Auxiliaries Utilized in Mixed-Pressure Turbine—Costs Reduced to 1.6 Cents per Kilowatt-Hour with Plant at Half Capacity

BY ANDREWS ALLEN AND H. F. HEBLEY  
Chicago, Ill.

SO MANY mines nowadays are operated on current purchased from a central station that it is a matter of considerable interest that a sizable operation, such as the No. 4 mine of the Donk Bros. Coal & Coke Co., in Madison County, Illinois, lying within easy reach of central-station power, is deliberately equipped with a generating plant of its own.

The decision to generate, rather than to purchase, power was made when the designs for this plant first were formulated. This was back in 1918 and 1919, when the power service in that field was subject to many interruptions. But it was reaffirmed far more recently, even though many improvements had been made meanwhile in central stations and in the service they render. This mine and its power plant were completed only last winter, but the mine had been operated since 1921, the hoisting capacity of the original equipment having been only 2,000 tons per day. At present, the mine can produce 3,500 tons of coal daily and has a hoisting capacity of 6,000 tons.

Since the original or partial installation was completed, there has been ample opportunity to study the conditions existing. It was, however, decided to follow

the power policy originally adopted and to operate the mine from an individual steam plant. In the meanwhile, one of the other mines of this company had been worked out and still another had been sold, leaving one good-sized property—No. 2 mine—still operating in addition to the new No. 4 development. The No. 2 mine has been partially electrified and is operating on current from No. 4.

### SPECIALLY DESIGNED PLANT GENERATES CHEAPLY

It was believed that a power plant designed especially for mining conditions and equipped to burn mine refuse, could produce power cheaper than it could be purchased. The results obtained up to the present time on partial tonnage bear out this conclusion. The general design of the plant, as described in *Coal Age*, of June 9, 1921, has been followed with certain minor improvements and modifications, which will be described.

The relative economies of a steam hoisting engine and an electric hoist at No. 4 mine were carefully considered from every possible angle. It was found that the power cost would be slightly in favor of the electric hoist and that the water requirements of the plant would be lessened by it, but the initial investment entailed by an electric hoist would be greater. It was, therefore, decided to install a steam hoist using a regenerator and a mixed-pressure turbine as a means of utilizing the exhaust steam from the hoist.

A compact and economical arrangement was obtained

NOTE—An article by the same authors describing the bottom and surface works of this mine appeared in *Coal Age* of June 26, 1924. The headpiece illustrates the eight horizontal return-tubular boilers in the Donk No. 4 boiler room. These are set in four batteries. Each battery is fired by one stoker. The large water capacity of this type of boiler guards against the heavy fluctuations of pressure caused by the intermittent operation of the hoisting engines.

by locating the main hoisting engines in the northwest corner of the boiler house in a space opposite that occupied by the boiler auxiliaries and the regenerator, the engine and the other equipment being separated by the firing aisle. By this arrangement the new batteries of boilers were set exactly opposite the old ones and the coal feed to them was taken from the same outlets in the coal bunkers above the aisle. The steam hoist draws its steam from one corner of the loop header and the turbines from separate outlets on the other side of the piping system, thus giving an excellent distribution of steam demand.

Return-tubular boilers were adopted in the first installation, because with them a large volume of water could be obtained to meet the sudden demands for steam imposed by the hoisting engine. The results obtained from the first two batteries of boilers were highly satisfactory, fluctuations in steam pressure within them being much less than could be anticipated with the same horsepower of water-tube boilers. This type of steam generator is eminently adapted to use in hoisting plants, and by utilizing battery settings, as in this instance, it is possible to obtain reasonably large units with fair economy of floor space.

The original power plant was equipped with two pairs of 78-in. x 20-ft. boilers having a total rated capacity of 800 hp. Each pair of boilers was set over a single stoker of the Harrington type.

#### UNITS WERE CHOSEN TO MEET PLANT NEEDS

The generating equipment originally installed consisted of one unit having a rated capacity of 450 kw. of 2,300-volt, 3-phase, 60-cycle alternating current. This unit was direct-connected to a Chuse 28x32-in. uniflow engine, which was operated non-condensing during the development period. A small 50-kw. engine-generator was also installed for lighting and miscellaneous service. A pair of 18x36-in. hoisting engines serving the auxiliary shaft and a steam-driven fan completed the major equipment of the first installation.

The boiler house is of steel-frame construction with walls of hollow tile. These are gunited on the outside and in the part used as an engine room are plastered on the inside. The boiler room is 92x100 ft. in plan and in the original construction was built so as to accommodate future units.

The size of the turbine room was increased somewhat from the original plans in order to provide for the new power units and for future units as will be described later. The completed building is 45x116 ft. and has a basement 13 ft. 6 in. high.

The completion of this plant involved a large increase in power capacity. The selection of units was made on the basis of a 6,000-ton output per day for No. 4 mine and a load varying from 900 kw. to 1,200 kw. as determined by a power survey of the No. 2 operation. In view of the large initial cost of an electric hoist for the No. 2 works, it was decided to leave the No. 2 steam hoist in place.

In planning this power house, the engineers had the unusual advantage of nearly four years of experience gained with the equipment originally installed. But, so satisfactory had been the operation that the original designs for and the arrangement of power units were followed without material change. It was decided, however, to add certain power-saving details to the original units, such as a condenser for the uniflow engine, superheaters for the original boilers and a clarifying sys-

tem for the water supply. These were omitted from the first installation, largely because their cost would not be warranted in view of the low tonnage obtained during development work.

The capacity of the original boiler equipment was increased by the addition of two batteries, which are duplicates of the original; each consists, as before, of two 78-in. x 20-ft. return-tubular boilers set over a single Harrington stoker. The plant now has a rated capacity of 1,600 boiler horsepower and when operated at 150 per cent of rating is capable of delivering regularly 2,400 boiler horsepower. This is sufficient for the operation of the No. 4 mine at rated capacity, together with the electrically-driven units installed at the No. 2 plant.

The grate area under each battery of boilers is 90 sq. ft., which is the same as that installed in the original plant. This gives a ratio of heating surface to grate area of  $33\frac{1}{2}$  to 1. The new settings are similar to the old, but the distance from the grate surface to the underside of the boiler shells in the new settings was made 7 ft. 3 in., which is slightly higher than in the old installation.

A concrete stack, 9 ft. in diameter and 136 ft. high, and a forced draft fan of 48,000 cu.ft. capacity when operating against a  $1\frac{1}{2}$  in. water gage, were both included in the original installation. They were regarded as ample to meet present requirements, although the general design of the plant provides for another stack and a duplicate fan should the load be increased by the addition of other mines.

This plant was designed to burn low-grade fuel, or that possessing little or no market value. The coal supply at the present time consists of crushed gob or pickings from the picking tables, together with the quantity of  $1\frac{1}{4}$ -in. screenings needed when enough pickings cannot be obtained. The provision for utilizing low-grade fuel is regarded as being of the utmost importance. First, it reduces fuel bills and, second, it tends to improve the quality of the coal produced at this mine.

The tendency at this operation will always be to pick thoroughly and to clean the coal well. Combustible pickings are not wasted, as at mines operated on purchased power, and the pickers consequently need not spend undue time in breaking up lumps in an attempt to separate rock from coal.

Fuel for the boiler plant is drawn from a small track hopper. This hopper can be utilized also for "foreign" coal or coal from the auxiliary tippie. It is fed by a conveyor from the main tippie where the gob and bone from the picking tables is crushed to  $1\frac{1}{4}$ -in. size and any deficiency in supply made up by the addition of  $1\frac{1}{4}$ -in. slack.

#### AUTOMATIC DRAFT AND STOKER CONTROL PROVIDED

The original forced-draft installation with its control mechanism was extended by means of ducts provided with proper dampers from the forced-draft fan. A curved breeching from the new boilers was connected with the stack. Both of these installations are adapted to connect also to a duplicate fan and another stack which may be required at some future time. The dampers, fans and stokers are all controlled by a balanced-draft system.

This equipment automatically maintains a draft of approximately 0.08 in. over the fire through proper regulation of the fan speed and the position of the

uptake dampers. Means for controlling the draft of the individual boilers is also provided through installation of stoker gates which insure the proper air pressures and volumes for the various compartments of the grate.

Approximately 150-lb. gage pressure is the maximum that can be safely carried with boilers of this type. This pressure is accordingly carried on these units and approximately 100 deg. F. of superheat is added. The superheaters are located in the rear combustion chamber. The new settings were fitted with superheaters when built, and superheaters were then added to the original settings. Ashes are removed by a steam-jet ash conveyor, which lifts them into a reinforced-concrete storage bin, from which they are loaded for disposal into cars running on a standard-gage track.

For the removal of soot from the flues, Vulcan blowers have been placed at the rear of the settings. These are fitted with elements that will operate on both the boiler and superheater tubes. The main steam header is a loop system of piping fitted together with

high has been provided. This is equipped with an automatic chemical-measuring device for introducing alum and caustic soda. The normal capacity of the settling system is 6,000 gal. per hour, allowing approximately four hours for flocculation and settlement of sludge.

#### ONLY FILTERED WATER REACHES THE PLANT

Under average conditions, approximately  $\frac{1}{2}$  lb. of alum and  $\frac{1}{2}$  lb. of sodium hydroxide per thousand gallons of water treated is required. It is necessary to clean out the sludge about every ten to fourteen days. Water leaving the settling tank is pumped through two pressure filters, each of 6 ft. 6 in. diameter and 6 ft. 10 in. high, to an elevated storage tank having a capacity of 40,000 gal. and affording a minimum head of 40 ft. From this tank, water is drawn for all plant purposes. The arrangement of the settling system is such that the flow of water is automatically controlled and regulated by the water level in the main storage tank. The make-up water for the power plant is further treated

FIG. 1

#### Power Plant

This plant now contains a high-pressure turbo-generator, a mixed-pressure turbo-unit, utilizing the exhaust from the hoist and various auxiliaries, and an engine-driven unit. All these machines are operated condensing. Provision has also been made for the possible future installation of another turbo-generator when the load on the plant becomes heavy enough to warrant it.

Vanstone flanges and large-radius expansion bends. Angle stop valves are installed on all outlets both to and from this header. These eliminate many fittings and obviate water pockets in the line. High-pressure traps handling the condensate from the steam lines return all drips to the feed-water heater. An auxiliary header supplies steam to the boiler-feed pumps and auxiliary units.

In order to enable the firemen to operate the plant to best advantage, meters have been installed upon each boiler. These indicate the flue-gas temperature, the percentage of excess air and the steam flow. A water-supply system was constructed several years ago, fed from surface drainage to a pond approximately  $1\frac{1}{2}$  miles from the plant. A portion of the watershed or drainage area consists of cultivated fields, and as a result the water usually carries much mineral matter in suspension. This water is objectionable, not only as boiler feed, but also for use in showers, wash basins and other plant facilities.

To eliminate the matter held in suspension, a 30,000-gal. settling tank 18 ft. in diameter and 18 ft. 4 in.

by a zeolite system, thus insuring clear water of practically zero hardness.

Treated water is sent to the boilers through a feed-water heater by means of a 12x8x12-in. steam-driven direct-acting duplex pump. This is controlled by boiler feed-water regulators with pressure governors on the pump.

The normal full-load generating capacity of this plant is 2,700 kw., made up of the following units:—One 1,500-kw., 0.8-power factor, high-pressure, turbo-generator, with direct-connected exciter; one 750-kw., 0.8-power factor, mixed-pressure steam turbo-generator, also with direct-connected exciter, and the original uniflow 28x32-in. engine unit, direct-connected, to a 450-kw. generator with a belted exciter. Although the original unit was run non-condensing during the development period, all machines are now operated condensing. Provision has also been made for the possible future installation of a third turbine, which will probably be of 2,000-kw. capacity.

Direct current is used underground. This is supplied from motor-generator sets installed within the

mine and fed by 2,200-volt alternating current through armored transmission cables. Storage-battery locomotives are used for gathering. They are charged on the second, or night, shift.

The established power requirements of this plant, including both electrical and steam loads, the latter including the requirements for heating the tipple and wash house, are shown in Table I.

Table I—Power Requirements at Donk No. 4 Plant

	Average Load, kw.	Sustained Peaks, kw.
Mine No. 2 only, already fully developed...	900	1,200
Mine No. 4 only.....	1,500	2,000
Mines Nos 2 and 4 combined.....	2,050	2,600
Mine No. 4, charging shift.....	650	.....
Mine No. 4 idle shifts.....	330	.....

At the present time, the load from No. 2 mine, when No. 4 is idle, is carried by the 1,500-kw. unit, or by the 750-kw. unit when running on high pressure. When only the No. 4 operation is running, the load is carried by the 750-kw. mixed-pressure unit supplemented by the 450-kw. machine operating condensing. When both mines are in operation, the 1,500-kw. unit is put into service in place of the 450-kw. machine. For the ultimate load, when both mines are in operation, the 1,500-kw. unit and the 750-kw. mixed-pressure unit, can carry the load supplemented, if necessary, by the 450-kw. machine, and for No. 4 mine alone the two turbines will easily carry the load.

#### SPACE PROVIDED FOR ADDITIONAL POWER UNIT

It will be noted, however, that an accident to any unit will seriously cripple the operation when the full load is on, and space accordingly has been provided for a 2,000-kw. turbine to be installed in future when the load begins to approximate the anticipated ultimate amount. This future machine supplemented by either of the other units easily will carry the entire load. When the ultimate load on the plant is attained, however, it also may be desirable to add a spare battery of boilers, although the four units now provided will carry the load at approximately 150 per cent of normal rating.

The water rates of the various power units are as shown in Tables II, III and IV.

All units are fitted with surface condensers. The uniflow engine is provided with a condenser of 1,220 sq.ft. of tube surface, a 1,250-gal. per minute circulating pump, and duplicate Radojets. The 1,500-kw.

Fig. 2—Steam-Driven Hoist

Investigation showed that an electric hoist would be slightly more economical than one operated directly by steam but would entail a much higher initial investment. A steam hoist accordingly was chosen. The exhaust from this unit is passed through a regenerator and thence through a mixed-pressure turbine.

Table II—Water Rate, 450-kw. Uniflow Engine

	Non-condensing, Lb. of Steam per Kw.-Hr.	Condensing, Lb. of Steam per Kw.-Hr.
$\frac{1}{2}$ load.....	29	19.4
$\frac{3}{4}$ load.....	27.9	18.5
Full load.....	27.9	18.5
Full load.....	29	19.1

Table III—Water Rate, 750-kw. Mixed-Pressure Turbine

	Low pressure, Lb. of Steam per Kw.-Hr.	High pressure, Lb. of Steam per Kw.-Hr.
$\frac{1}{2}$ load.....	47.9	26.2
$\frac{3}{4}$ load.....	42.0	22.3
Full load.....	41.0	20.5

Table IV—Water Rate, 1,500-kw. High-Pressure Turbine

	Lb. of Steam per Kw.-Hr.
$\frac{1}{2}$ load.....	19.4
$\frac{3}{4}$ load.....	18.5
Full load.....	18.6

unit and the 750-kw. unit are provided with condensers of 4,000 sq.ft. tube surface and 3,500 gal. per minute circulating pumps with Radojets and after-condensers.

Air for circulation through the turbo-generators is purified by an air washer located in the basement of the power house. All turbines are set on steel supports composed of box sections filled with concrete. These provide a setting for the various machines and their condensers that is independent of the floor.

Low-pressure steam for operation of the 750-kw. mixed-pressure unit is drawn from the exhaust of the main hoisting engine, the auxiliary hoisting engine and other plant auxiliaries with a view to utilizing all the steam not required for feed-water heating. The operation of the hoisting engines is necessarily intermittent, and in order to furnish a continuous flow of steam to the mixed-pressure turbine, a pair of regenerators, each 9 ft. in diameter and 25 ft. long operating in parallel and set one above the other, have been interposed between the exhaust-steam header and the turbine.

The flow of the exhaust to the regenerators is controlled by a flow valve, which is adjusted to maintain automatically the pressure in the exhaust-steam system between the engines and the flow valve at a minimum of 1 lb. This has been done in order to assure a sufficient supply of exhaust steam for feed-water heating. It provides a uniform temperature within the feed-water heater of approximately 205 deg. F.

Each regenerator stores 600 lb. of steam when the pressure falls from 18 lb. per square inch absolute to 14.7 lb. When the pressure is 19 lb. per square inch absolute and drops to 14.7 lb. per square inch, 700 lb. of steam is available. Any excess of steam after the regenerator and feed-water heater requirements have been filled, is vented to the atmosphere through a specially designed back-pressure valve.

#### CIRCULATING WATER COOLED IN A SPRAY POND

Should the supply of exhaust steam fail, because of the hoisting engines not being in service, high-pressure steam is automatically cut in and supplied to the mixed-pressure unit when low-pressure steam drops to a predetermined point, or, in other words, whenever high-pressure steam may be required for carrying the load.

The available supply of water for condensing purposes, as is frequently the case at plants located in this region, was limited, and it was accordingly necessary to provide a spray pond for cooling the condenser water.

FIG. 3

**Spray Pond**

Water for condensing purposes is obtained only with difficulty at many mines. By using a spray pond the circulating water of the condenser may be used over and over again sustaining losses only from evaporation, from leakage and from the blowing away of spray by the wind. These losses readily are replaced. Such a pond gives best results when the atmosphere is dry and its poorest results when it is humid. Under ordinary circumstances, however, it affords fairly satisfactory service regardless of weather conditions.

As this pond is located opposite the power house and just across the mine tracks from it, the pipes to and from the pond are carried under the railroad fill. The condenser water is circulated by motor-driven centrifugal pumps. The spray pond is 100x271 ft. in plan and 264 spray nozzles are installed over it.

Sufficient spray-pond capacity is provided for handling 10,500 gal. of water per minute when a pressure of 7 lb. per sq.in. is available at the nozzles. This gives a capacity of 40 gal. per minute per nozzle at the pressure named.

The switchboard installed in the power plant is of the remote manually-operated type, with all switches mounted on separate pipe framework in the rear of the panels. This switchboard is located in a lean-to so that the board is flush with the south wall of the power house. Three-phase, 60-cycle alternating current is generated at 2,300 volts and fed to the various loads as required.

Banks of step-down transformers reduce the voltage from 2,300 to 220 for all motors installed on the surface as well as for lighting in both auxiliary and main tipples. An outdoor step-up substation composed of three 333-kw. single-phase transformers raises the voltage to 33,000 for transmission to the No. 2 mine at Maryville.

At mine No. 2 a step-down station of the same capacity, as that above described, reduces the voltage to 2,300 at which potential current is supplied by way of a borehole to 2,300-volt alternating-current, 265-volt direct-current synchronous motor-generator sets installed within the mine. These machines supply direct current to the mining machines and haulage locomotives.

The underground load at mine No. 4 is served by a 2,300-volt line extending down the auxiliary shaft to synchronous motor-generator sets installed at strategic points underground in a manner similar to that followed at mine No. 2. By using these synchronous motor-generators and giving them a leading power factor, the power factor of the whole plant is held

approximately at unity, notwithstanding the fluctuating loads that are encountered.

The operating results obtained at this plant have thus far proved highly satisfactory. Power costs have been reduced month by month until, with a tonnage at No. 4 mine scarcely more than half its rated capacity, the cost per kilowatt-hour for power used at both operations has been reduced to 1.6c. This includes all plant labor and maintenance with a suitable proportion of the total executive and clerical expense. It includes also interest and amortization of the power plant and its equipment, as well as coal charged to the plant at the regular market price, although at least one-third of the fuel now burned consists of pickings which not only have no commercial value, but which otherwise would have to be disposed of at an additional expense.

The operating executives of the Donk Bros. Coal & Coke Co., under whose direction the construction and development of this mine and plant was performed, are: Edwin H. Conrades, president; Edmund C. Donk, vice-president; and Walter J. Clark, general superintendent. The plant was designed and constructed by the Allen & Garcia Co., of Chicago, under the immediate supervision of Wayne O. Axtell, resident engineer. From the results already secured, it is fair to predict that power and mining costs will be materially reduced from their present levels when the tonnage of the mine approaches its normal rating.

THE UNION PACIFIC COAL CO. has eliminated black powder from its mines. It is extending its water lines to the face of the workings so that all loaded cars may be drenched before they are started out of the mine. As has been announced adobe or rock dust has been spread in the mines, the work having been under way for six months. This will be completed by the fall when the low humidity season sets in. All mines known to be gaseous are being run on 100-per-cent closed lights and an order for 2,100 additional electric lamps has been placed to make the installation complete in both the gaseous and non-gaseous mines of the company.

*Tipple at Gebo, Land Leased from U. S. Government*

## U. S. Rules Make Mines in Public Lands Safer

Regulations Could Not Go Into Detail to Meet All Conditions in Forty Million Acres of Coal but Sound General Principles Are Covered Benefiting Miner, Operator and Public

BY H. I. SMITH

Mining Supervisor, U. S. Bureau of Mines  
Denver, Colo

**P**REPARING regulations for coal mining on leased public lands in the United States was no simple matter. It was difficult indeed to frame rules applicable to mining in all the coal deposits in the 40,000,000 acres under government control but the general principles of good mine operation were covered with safety especially in mind. The regulations, as they now apply in the 670 leases on more than half a million acres in fifteen states are believed to be absolutely sound and fair, beneficial alike to miner, operator and the public. I cannot go into all the details of the regulations but after tracing their history, I want to touch upon some of their features which have to do with safety.

In 1913, the Secretary of the Interior charged the Director of the Bureau of Mines with the duty of inspecting the physical operation of coal, asphalt and such other mines as belong to the Indians and Indian tribes wherever located and to draft necessary rules and regulations from time to time regarding the operation of leases over such Indian lands and all other lands leased by the Department of the Interior for mining purposes or operated subject to its approval. These regulations must be submitted to the Department for its approbation.

The first regulations, prepared by the Bureau of Mines, and applicable to coal mines on public lands, were approved May 10, 1913. They applied to the lease

of the Owl Creek Coal Co. in Wyoming, which lease was granted by special act of Congress. The only other lease operating on public lands, other than in Alaska, prior to 1920, was that of the Victor American Fuel Co., to which a lease was granted by a court decision. This lease was supervised by the General Land Office. The operating regulations applicable to leased coal lands in Alaska were the second set of rules which the Bureau assisted in preparing. They were approved May 18, 1916.

### BUREAU MAKES REGULATIONS FOR LESSEES

When the act of Feb. 25, 1920, was passed permitting the leasing of coal, oil shale, phosphate, soda, oil, and gas on public lands, the Bureau was delegated to prepare the operating regulations necessary, in accordance with Sections 30 of the Act, which reads in part as follows:

Each lease shall contain provisions for the purpose of insuring the exercise of reasonable diligence, skill, and care in the operation of said property; a provision that such rules for the safety and welfare of the miner and for the prevention of undue waste as may be prescribed by said Secretary shall be observed.

In the preparation of these regulations invitations were sent to the American Institute of Mining and Metallurgical Engineers, the American Mining Congress, the National Coal Association, and to the governors of eleven public-land states, to appoint representatives to attend a hearing at Washington. Prior to the date set for this meeting, regulations were prepared as a basis. These were considered one at a time at the session and were discussed at length.

From the minutes of the several sessions a second

NOTE—This article is constructed from a paper read by Mr. Smith at the February meeting of the Rocky Mountain Coal Mining Institute at Denver. The headpiece shows the oldest lease on Government lands, granted by a special act of Congress, Aug. 1, 1912. This mine, which is owned by the Owl Creek Coal Co., has the biggest production of any mine operated on lease from the United States. In 1923 this plant produced 293,424 tons. Illustrations furnished by courtesy of Goodman Manufacturing Co.

set of regulations was prepared and re-submitted by mail to the delegates and other prominent mining men for their further comment. These comments were carefully tabulated and in general the prevailing opinions were adopted. Whenever possible, the exact wording of some one of the delegates was used. The regulations now in effect were approved by the Secretary of the Interior, April 30, 1921, and are now just as much a part of the contract as any other paragraph in the lease.

I will not refer to the policy of Congress or to the history of how the United States retained control of 40,000,000 acres of coal land. I use the term "control" qualifiedly, as 37½ per cent of all the income goes direct to the state in which the land is located; 52½ per cent is appropriated to the Reclamation Fund; and only 10 per cent for supervision is retained by the Government.

There are on this area at the present time under lease or applications for lease, coal beds as thin as one foot in thickness to beds 100 ft. thick; some beds lie horizontal, others are practically perpendicular. Almost any dip between these extremes can be found. The cover varies from stripping operations where the dirt

**Locomotive Pulling Trip of Empty Cars at Gebo**

Four 6-ton, two-motor locomotives operate on the comparatively level cross headings and haul trips of from 45 to 50 cars to the main slope taking them from the various partings on the cross entries. Only alternate sets of levels become electric haulage roads.

favorable to making changes in mining methods. Again, it was impossible to change a mine which had been in operation for many years, except to modify the projected plans and working conditions and provide for the required safety features.

I do not wish to enter into too much detail in discussing the application of the rules to the leased public coal lands and to mining operations on public lands covered by prospecting permits, but I do wish to discuss briefly a few of the things which, from our inspection of mines on leased lands or adjacent to leased lands, should be stressed even though some of them may be considered as old subjects.

Those topics which I have chosen relate to fireproof buildings, electric installations, explosives, explosions, rescue apparatus, and mine maps.

#### MINE MAPS SHOULD SHOW MINE PROGRESS

I have placed mine maps on the list as matters of leading importance because I wish to emphasize the fact that maps only rarely show such data as will enable the owners of the mine mapped, when they are called on by tax authorities, to show the depletion for the several tax periods. The maps usually made will not inform the owners what percentage of coal per acre has been mined, the condition of the abandoned

**Shortwall Machine Cutting up Pitch in Gebo Mine**

The seam at Gebo is inclined at an angle of 22 deg. to the horizontal. The rooms are arranged so that the coal is cut up the full pitch of the seam, the roads being laid on the strike of the measure and the main haulage road, which is laid with 60-lb. steel, going down the pitch of the seam.

is shoveled off the coal by hand to coal under an overburden of more than 2,000 ft. The grade of the coal ranges from lignite with 40 per cent of moisture, to anthracite. The size of operations range from a required production of 275 tons to 200,000 tons per year. This article will not deal, however, with many of the difficulties thus arising.

Since Feb. 25, 1920, under the provisions of issuing leases, licenses, and prospecting permits, 670 grants have been made, comprising more than one-half million acres of coal lands in fifteen different states. All of these grants are west of the Mississippi, with the exception of one lease in Alabama. Of this number there are 116 coal leases in eight different states, covering 60,000 acres.

The regulations necessarily had to be rather flexible for the natural conditions on the public coal lands vary as widely as coal-mining conditions could vary. The mining laws and mining practices in the several states varied widely. The attitude of labor was not always

**Gathering Hoist Pulls Car from Room, Gebo Mine**

Car is pulled by a hoist, located beneath the light in the end of the heading, uphill from the room neck and then is lowered down the stub slope to the parting on the level side entry. The steeply pitching mines of the Rocky Mountain region still use rope haulage extensively on the pitches but all the level haulages are by electric locomotive.

workings or what progress was made in the operation of the mine from year to year.

The production requirements of the leases granted have been, with few exceptions, based on a life of 50 years, so that, as a matter of good business, it is essential that the construction of temporary buildings of the firetrap nature be discouraged and that buildings be more of the fireproof type. The regulations provide that flammable buildings shall not be placed within 75 ft. of any mine opening. However, some consideration must be given to cases where the nature of the mine is such that the operation of the property will be only temporary.

With reference to wash-houses, one cannot imagine how quickly after a wash-house fire, a pair of burned overalls and a dirty shirt jump to the value of a dinner-suit and a silk shirt. The claims for lost watches and rolls of money are astonishing. After such an experience in a mining community, when many thousand dollars are claimed and lawsuits threatened, the local

Electric power is of such importance in American mines that the mining men of the present day are not attempting to increase safety by eliminating electricity, but by making conditions such as will be safe with the present electrical equipment, but if this cannot be done, the endeavor is to get electrical equipment which will pass tests entitling it to be termed "permissible" under the conditions to be imposed.

At the hearing in Washington, I can recall but one person who advocated higher than 300-volt current for portable machinery, and so 300 volts was set as the maximum voltage to be used on portable electrical machinery in the mines on public lands. However, mines equipped with higher voltage at the time of obtaining a lease may be permitted to continue its use upon petition to the Secretary through the mining supervisor.

Some thought that lead-covered cables in a conduit might be satisfactory for conducting high voltages underground, but analyzing the cost and the added

#### Gebo Man Trip

Men are lowered down the main slope in a train specially constructed for that purpose. They sit in such a location on the car that they are not likely to be struck by overhanging rocks at the side. With good seats men are not likely to burn one another with their carbide lights or be injured as they are when entering the mine on the regular trip.

management takes stock of all the buildings and starts a fireproofing campaign.

Fires start in wash-houses, as well as in other buildings, from spontaneous combustion and so every endeavor should be made to keep wash-houses clean, and no old clothing or towels should be permitted to be discarded and left where they may come in contact with steam pipes, or be deposited in any place where they will not be sufficiently well ventilated to prevent spontaneous combustion. One of the greatest fire hazards in a wash-house is present where the mine management permits those using the wash-house to put their towels or other fabrics on the steam pipes to dry. This is especially true should the clothing be oily.

The steam pipes should be sufficiently far from any contact with wood as to eliminate the chance that accumulations of lint will become ignited and set fire to the wood. Though the pipes should be protected to keep those using the wash-house from getting burned, the guards should be open to permit of radiation and to lessen the danger of fires.

safety, both to the employees and to the property, it was considered advisable to require an armored cable for all 2,300-volt circuits.

In regard to electrical installations, I wish to make two recommendations: First that a special color of insulation tape be used on high-voltage wire connections in power stations both on the surface and underground. As yellow has been adopted by a number of coal companies for this purpose, it is recommended that this practice be continued so that any newly employed electrician in a mine can tell at a glance which are the high-voltage connections. Black tape then should be used only for low or medium voltages.

Secondly, as alternating current rapidly has been replacing direct current for operating mining machines, I would advocate the use of a three-strand cable in place of three single wires. The more closely together these wires can be placed the less loss of power, and if all three wires are in a single cable, the accident hazard is reduced. The cost of stringing the single cable will almost balance the difference in cost.

### How to Plat a Mining Working Historically

Some map makers use dates showing progress of development and coal extraction but a date, like a large number on an automobile is not desirable. A letter takes the eye more easily and conveys the message more rapidly. It also takes less room and when the map is photostated to a small size the letters are still legible. Maps today should be drawn with lettering that will make necessary information decipherable on a photostat of any dimension likely to be made.

There are many instances where electricity has been instrumental in igniting black powder, both in transit and at the working face. As a result, many employees have been suffocated and a number of dust explosions initiated. Consequently too much precaution cannot be taken to protect powder at the face adequately and to insulate all cars used for its transportation. Though the operating regulations permit the use of black powder under certain restrictions, the sooner it is entirely eliminated the safer it will be for mine employees and the less the loss to the operators in fires and explosions.

During the Pittsburgh meeting of the Coal Mining Institute of America in December, 1923, a demonstration was made to show how quickly a keg of powder would explode when brought in contact with electric current. Two empty powder kegs were laid on a block of wood with a wire connected to each keg. A full powder keg was laid across the two empty kegs, and the current turned on. The top keg was pulled by a rope so that a movement was imparted similar to that which it would get in a car. The keg exploded almost immediately after the first movement.

Mines are being rock-dusted as a means of preventing explosions in Pennsylvania, Illinois, Oklahoma, Wyoming, New Mexico, Colorado, Alabama and probably in other states. The English law, as is well known, requires that there shall be in all road and rib dust at all times not less than 50 per cent incombustible material. As a result of this law, all of the several explosions in Great Britain occurring during the past year were blanketed within a short distance from the point where they originated.

### EVERY UTAH MINE MUST HAVE RESCUE APPARATUS

The state mining law of Utah requires rescue apparatus to be available for each coal-mining operation where fifty or more men are employed. The value of such apparatus can be appreciated only by operators who have had real emergencies of this character and who had previously provided such apparatus for their mines. The regulations require that at every mine in which more than one hundred persons are employed underground on any shift, the lessee shall have kept and maintained at the mine in order, ready for use, not less than five sets of oxygen or self-contained breathing apparatus. Many of the present lessees had equipped

themselves with mine-rescue apparatus prior to obtaining a federal lease and only a few have hesitated to comply with these provisions of their lease.

The regulations require that the mine maps be posted periodically. Some engineers keep maps showing the area mined over each extension period. This method requires a large number of maps. Other engineers use various methods to show where the room and entry faces were at the time of each extension. Some maps we get do not indicate in any way where the faces are at any time, except at the time of the last survey.

The method which appears to me to give the clearest picture of the mine and its history and to show those things which the Government requires shall be on the map of every lessee, is that worked out and used by H. P. Dyer, general manager and chief engineer of the Vandalia Coal Co., at Terre Haute, Ind.

The sketch which accompanies this article shows that in place of putting the dates at the face of the entry and rooms at the time of each extension, letters are used consecutively for each survey with the reference date on the margin of the map. A light line is drawn across the face of each room and entry, and the letter is put on the outby side. If the place is being worked at the time of survey, the ribs are extended beyond the face. If the place has been stopped there are no projections. Should the room or entry be caved or be inaccessible to the surveyor, the distance to the face is obtained as closely as possible from the mine boss or other reliable source, and the projection is shown in dotted lines.

Following the letter showing the projection on the entries, the section of the coal bed is given. Only the number of each fifth room is shown. Hatching is used only to show pillars actually extracted. The hatching does not extend over the room, nor does it cover stumps that the mine boss did not recover. This latter provision is important should any squeeze develop.

The Act of Feb. 25, 1920, requires in addition to periodic maps, that the elevation based on sea-level data be shown at 500-ft. intervals. Elevations and contours normally should be shown on separate maps.

All of the requirements under the regulations are of as much value to the operator as to the Government, and it is hoped that lessors of these public coal lands will realize this and co-operate more fully with the Government, in carrying out the regulations to the full.

Plan of a Section of the Mine Workings at Gebo

This shows the method that has been found most satisfactory in Wyoming where the measures quite generally pitch heavily. It has been found more economical and much safer to lay out the rooms on the strike of the bed. The main slope is equipped with a 2,000-hp. cylindrical-drum steam hoist located practically on the plane of the coal floor and equipped with a 1½-in. steel rope. It pulls out a trip of ten loaded cars, weighing 7,500 lb. each, 80 to 90 trips being made each eight-hour day. The hoist is probably the most powerful in Wyoming. Small electric drum hoists are placed at the head of the butt slopes.

## Fatality Rate Per Man and Per Ton Sure to Decrease

Industrial Accidents as a Whole Have Increased—  
Rapid Extraction Reduces Loss of  
Life in Pillar Work

BY NEWELL G. ALFORD  
Consulting Engineer, Pittsburgh, Pa.

IN THE last year industrial-accident rates generally have increased, but there has been no appreciable increase in our coal-mining fatalities over the past decade. A recent publication\* cites that more than half the compensation states, representing all sections of the country, show an increase in industrial accidents of from 6 to 53 per cent, with an average of 29 per cent for all those reporting.

About coal mining, it is stated that "we are killing miners in the United States three times as fast as they kill them in Great Britain."† It is not mentioned, however, that we are mining slightly more than twice as much coal as Great Britain with 60 per cent as many men exposed to the hazards of mining. While the quantity of coal produced per fatality is not a proper measure of relative safety, the coal production per fatal accident in the two countries compared for 1920 is—

Great Britain—206,553 net tons coal (all kinds).  
United States—244,828 net tons bituminous coal.

Table I gives the fatality rates per thousand of men employed in coal mining in Great Britain compared with bituminous mining in the United States from 1873 to 1921, inclusive. Of particular interest is the fatality rate for falls of roof and coal, also shown in Table I. More than half the fatalities are caused by roof falls, and though the annual number of fatal accidents from this cause has changed but little in the last fifteen years, as shown in Table I, there has been an enormous increase in mining without a correspondingly increased sacrifice of life.

### AFTER ALL ROOF FALLS LEAD FATALITY LIST

Fatalities from roof falls deserve greater attention because they comprise over half of all the underground fatal accidents from all causes and, in a large majority of the localities, over half of all accidents from all ordinary causes. Table II gives the division of roof-fall fatalities, distributed by classes of work, and Table III gives a distribution of all fatalities by location. Both of these tables represent about 60 per cent of the Pennsylvania bituminous production for the periods they respectively cover, with the addition, in Table III, of data from two large companies in other states.

Table II shows work of mining and loading of coal to be most hazardous and the information in the first five lines and lines 8, 9 and 10 of Table III shows the hazard on pillar extraction to be greater than that in advance work for the usual methods of pillar extraction.

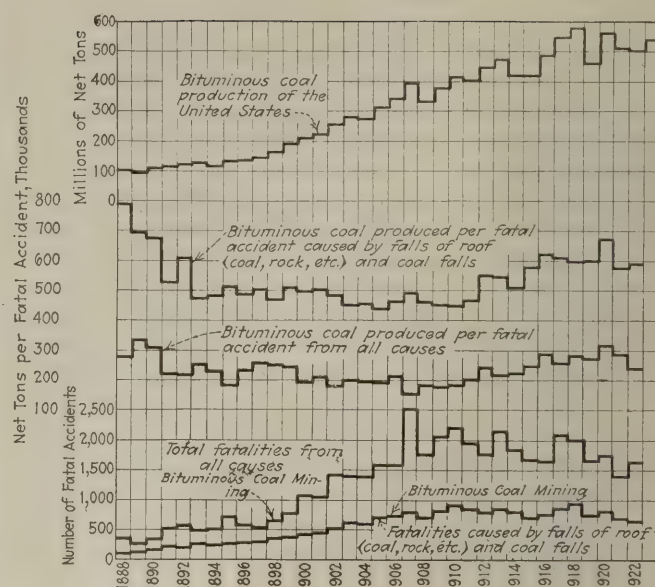

In Table III, the hazards from falls, in Pennsylvania mines, based on lines 1 and 2, is three times greater in pillar extraction than in advance work;  $(209 \div 15.6) \div (266 \div 59.7) = 3$ .

At Gary, W. Va., under Colonel O'Toole's manage-

NOTE—Article entitled "Engineering and Coal-Mine Accident Prevention," read before the West Virginia Coal Mining Institute, Elkins, W. Va., June 17-18.

\*American Labor Legislation Review, June, 1924, page 180.

†John B. Andrews, "The Annals of American Academy of Political & Social Science," January, 1924. Coal Production of Great Britain, 1920—254,060,302 net tons. Coal Production of United States, 1920—568,000,000 net tons.

Bituminous-Coal Output, Tonnage per Fatality from Falls and from All Causes, Total Fatalities

Though more tons of coal were mined per accident both from falls of roof and all causes in the late eighties and early nineties, we are doing better by far than in later nineties and in the first ten years of the present century. The safety campaign has done much. It is destined to do more. Not only is the downward swing in safety arrested but speaking broadly, overlooking the last two years an upward swing has taken its place.

ment, where slightly under 60 per cent of the men on coal are on pillars, the hazard from falls in pillar extraction, based on data in lines 6 and 7, is one-fourth of that on advance work;  $(28 \div 41.7) \div (9 \div 58.3) = 4$ .

In the third illustration, lines 8, 9 and 10, the hazard from falls is twice as great in pillar extraction as in advance workings.

The roof conditions at Gary are by no means better than the average, 11 per cent of the coal tonnage handled represents the actual quantity of slate that is hauled outside and dumped, in addition to fully as much more slate, rock and rash that is gobbled inside. The draw slate over the No. 3 Pocahontas Seam is particularly dangerous, holding "kettle bottoms," immediately over the coal, the shape of truncated cones ranging from 2 or 3 ft. to sometimes 10 or 12 ft. in diameter on the bottom.

When a place is first excavated, it is almost impossible to discover them, whereas in the second mining they have either partly settled in the pillar coal or dropped on the fallen coal before it is loaded out. These

Table No. I—Fatality Rates in Coal Mining Per 1,000 Employed

	Killed by Roof and Coal Falls		—Killed—All Causes—	
	Great Britain	United States	Great Britain	United States
1873-1882	1.12	1.44	2.24	3.18
1883-1892	1.00	1.25	1.81	2.68
1893-1902	0.76	1.48	1.39	2.98

Total.....	568	70	733	1,371

Does not include 181 fatalities from sliding coal, falling objects, etc. Arranged from Table XVI, "Statistical Analysis of Coal Mine Accidents in Pennsylvania 1916-1922, incl.," by Rush N. Hosler, Harrisburg, Pa.

conditions are met with careful and systematic timbering, based, on Colonel O'Toole's precept that all roof is dangerous. Close supervision of the men on coal and adequate lighting of the working places have also largely shared in greater safety from falls in pillar extraction.

Though the standing age of roof is universally recognized as a most important factor in roof-fall accidents, there are at present no actual figures to measure the direct relation to either accidents or fatalities in terms of lapse of time following excavation. It is a fact, however, that the more rapidly an area is worked the less is the danger from roof falls, and that the greater degrees of concentrated mining carry closer supervision and decreased exposure to the men.

The data in Table III, about Colonel O'Toole's mines, probably represents a far greater degree of concentration than any similar aggregate tonnage mined elsewhere, and it is known that the roof-fall accidents in pillars have been very largely reduced by those particular methods of working.

Properly used, mechanical loading will increase the possibilities of concentrated work. Over 2,000,000 tons

of coal were mined with the "Coloder" by the Pocahontas Fuel Co. with only one accident of any kind, and this case was a broken ankle. With the "Coloder" it is found that the timbering is less because the machine will load as much coal in an hour as two men will load in two or three days, and the machine will get out the coal before the roof has had time to settle. With the same roof conditions, in hand loading, the roof probably would fall at least once and would have to be cleaned up and retimbered before the coal could be loaded out.

Anything that will reduce the number of men employed and increase the output per man will reduce accidents, and as greater degrees of concentration in mining prevail with efficient application of machinery, accidents in coal mining are certain to decrease.

## Washing Ribs Before Rock Dusting

T. G. Fear, general superintendent, Inland Collieries Co., Harmarville, Ind., in a recent letter says that it is not necessary to wash ribs before rock dust is deposited. If the rock dust is applied before the ribs and roof are entirely dry the dust will cake and the benefit of the rock dust will be entirely lost as far as the extinguishing of flame is concerned. The only benefit to be derived from the dust thus deposited on the rib is that by reason of the washing there will be no coal dust to propagate a flame.

The main shaft bottom at the Indianola mine was recently rock dusted. The double-track loaded side is timbered with steel I-beams, placed 5 ft. apart, and coal dust has been accumulating on these beams. When this place was rockdusted most of the coal dust was blown off the timbers and on the floor farther along. An examination of the ribs and roof along the main north entry does not show any deposition of coal dust, "this," says Mr. Fear, "proving my theory that the very fine coal dust when placed in suspension with fine rock dust makes a mixture that is precipitated to the floor."

**Table No. III—Hazard in Pillar Extraction**

Location	Fatalities from Falls					Fall Fatalities per Cent	In-side Men per Cent

Data in lines 1, 2, 3, 4 and 5 from Table XIX, "Statistical Analysis of Coal Mine Accidents in Penna., 1916-1922, incl.," by Rush N. Hosler, superintendent, Coal Mine Section, Pennsylvania Compensation Rating and Inspection Bureau, Harrisburg, Pa.; Table XX and XXIV same book and from supplementary information supplied by Mr. Hosler in correspondence. Mr. Hosler's data represents 1159, 1549 and 1743 in 1920, 1921 and 1922 respectively and in round numbers about 60 per cent of Pennsylvania's bituminous production or an approximate yearly average of 80,950,000 tons.

## Practical Calculus for Home Study

To most engineers who have graduated from a mining college, calculus is a study long forgotten, but many problems yield readily to its use and occasionally the engineer needs to use it. To those who wish to study it or brush up on it a book entitled "Practical Calculus for Home Study," by C. I. Palmer, associate professor of mathematics, Armour Institute of Technology, is commended as calculated to serve to make that study pleasant and productive. The author makes his explanations plain and the subject intriguing. He illuminates a form of knowledge regarding which American engineers have been only too indifferent but which will amply repay study. The book measures 4½x8 in., has 443 pp. and costs \$3. The publisher is the McGraw-Hill Book Co., 370 Seventh Ave., New York City.

MILL TAILINGS from the concentrator at Morenci, Ariz., of the Phelps Dodge Corporation, are being used for rock dusting the coal mines of that company near Dawson, N. M. The tailings are sacked and shipped to Dawson. No rock is being ground for the dusting of these mines.

# Mining Industries Especially Are in Need of Trade Associations\*

The Truth About Profits, Breadth of Ownership and Variations in Costs Between Mines Should Be Taught the Public—Internal Affairs Need Association Service Too

BY GOLDTHWAITE H. DORR  
New York, N. Y.

THE natural-resource industries employ something like a million and a half men and probably seven millions of our population are directly dependent on them for a livelihood. In terms of dollars, the annual flow of this stream meters well over four and a half billion. The number of those who as stockholders are furnishing the billions of capital necessary for the conduct of these enterprises probably is almost as great as the number of persons employed in those industries.

Some of us had occasion a year ago to gather statistics which showed with reasonable assurance that there are substantially 350,000 individuals who are direct investors in the bituminous-coal mines alone. Much of the capital in these natural-resource industries is furnished by bondholders and other indirect investors, so that the actual number of persons whose savings are at stake in their sound and successful conduct equals, as has been said, the number of wage earners employed in them. If people could be made to see this fact many misunderstandings of the public would be resolved that now create the gravest problems of trade associations in natural-resource industries. The public does not know the business facts of these industries.

It is the prime field of usefulness of a trade association to collect and distribute the facts of the industry—facts useful to the industry itself in the intelligent operation of its business, useful to the consumer in the intelligent operation of his business, useful to the public in understanding conditions in the industry and making decisions as to its own relations with that industry. But during the last four years public opinion and government have challenged the very exercise of this vital function of trade associations. Why do business men and economists fight for the exercise of this function? Why has it been attacked?

There has been in the last quarter century nothing short of a revolution in the conception of business by business men. Their horizon has widened enormously. Development of industry and the pressure of competition, national and international, has led to a conception

of business as a science, in which the careful analysis of all available facts is taking the place of rule-of-thumb, hit-or-miss methods.

Efforts have always been made by business men during times of broadening markets to find out what others were doing, but the very absence of normal means for

mutual information led to mutual distrust and to the use of questionable methods. This situation, which rendered business highly speculative and which was fraught with disaster to producer and consumer alike through ungoverned fluctuations, grew intolerable with the broadening markets in the decades after the Civil War. To escape from it business men at the end of the nineteenth century turned to the creation of combinations and huge corporations, which through their

---

## THE TRADE ASSOCIATION'S "COMEBACK"

---

Although vilified and blamed for profiteering and almost scrapped after the war, the legitimate trade association is now compelling itself upon industry and business by sheer merit, Mr. Dorr thinks. No less an authority than the U. S. Supreme Court is finding for it, as in the glass and sugar exchange cases last winter. It is now for the trade association to rise to the place that awaits it, especially in an industry composed of so many small units as is the coal industry, and satisfy the demand of business men for less blind recklessness and more science in their affairs.

---

very size would have the necessary information to steer a sound business course. This tendency toward single large units probably would have fallen of its own immensity had its collapse not been brought about by the Sherman Anti-trust Law. It soon was discovered that on the whole it was more in accord with the genius of American institutions that there remain the initiative and competitive activity of smaller units.

But the need for *facts*—the common interest in having the facts in order that business might be conducted not as a poker game but in accordance with the scientific genius and bent of our people and of the age—made business men recognize that there was a common interest in gathering these facts. This led to the trade association. The need for their service, the sound economic results to be obtained were, before the Great War, clear to officers of government, the courts and business men alike. Indeed, the Federal Trade Commission at the start carried out the purpose for which it was set up—that of leader, helper and guide to business—by emphasizing, preaching and encouraging the trade-association movement, the collection and dissemination of current business facts.

But for the Great War the orderly development of this movement, it is fair to say, would have gone on. During the war industry generally came under the control of the government. At the end of the war, when that control was released, the inflation which had occurred during the war was followed by a secondary

\*An article constructed from an address delivered by Mr. Dorr before the natural resources production division of the United States Chamber of Commerce, Cleveland, Ohio, May 7.

period of still more extravagant inflation. Prices soared far beyond both war and pre-war levels. A general feeling of resentment spread through the country. Looking around for a cause of high prices the people blamed trade associations at once and charged them with some responsibility for profiteering.

As a result of a post-war witch-burning spirit, the trade association, a great accomplishment of American business men, a great piece of economic machinery, capable of serving producer and consumer alike, was attacked, vilified, discredited and almost scrapped. But I venture to say, that the tide has turned.

The Supreme Court during the past winter, twice has rejected unanimously the extreme interpretation of the Department of Justice of the Sherman Law in the important Glass and Sugar Exchange cases. There is no decision of the Supreme Court which holds that the collection and dissemination of trade information on the principles laid down by Secretary Hoover is in itself a violation of the Sherman Law, and I am prepared to venture the opinion that there never will be.

The particular facts common to natural-resource industries and having a direct bearing on trade-association activities in these industries should be reviewed.

#### ASSOCIATIONS CAN SERVE A COMMON INTEREST

Natural-resource industries are wasting industries. The most valuable mines will one day be worthless. From this it follows that methods of production and distribution and the economic organization of the industry should not be wasteful of the natural resource. Though the offense against conservation is more often waste in consumption than in production, nevertheless there is here a common interest within the industry itself and in the nation at large that trade associations in these industries should serve.

The interchange of technical information, so that the best available practices shall prevail, is important, and in this the trade organizations have been and can be of service, but there is the more fundamental problem that the industry shall not be so organized that there shall be in it recurrent extremes of oversupply and shortage. These produce a wastefulness in the production of the natural resource itself and of the nation's capital. To a solution of this phase of the problem the trade association can also contribute by the gathering and dissemination of trade information.

A second circumstance is that in these natural-resource industries there are multitudes of owning and producing units scattered over an enormous territory, often remote from market and having little opportunity to gage market conditions correctly. In bituminous coal, for example, there are over six thousand separate organizations. The larger units, perhaps, can, from their own wider experience, gage business conditions with reasonable accuracy, but the large number of small units are at a disadvantage unless the facts of the industry as a whole can be collected and disseminated among them through trade-association activities.

Third, there probably is keener and fiercer competition in natural-resource industries than in any other industries of the United States, and this competition often is carried to extremes that are destructive of the interests of owner, worker and consumer alike.

The public misconceptions which prevail as to the existence of competition in natural-resource industries are remarkable. We have the familiar popular myth of the coal trust in the bituminous industry, which

probably still persists in spite of ruinous prevailing prices and the finding of the Coal Commission that the industry is highly competitive, and that such periods of price inflation as have occurred were not in any way due to combination but to shortages in supplies due to the stoppage of production by strikes and transportation difficulties.

Trade associations in natural-resource industries can perform a very definite service in gathering and keeping before the public the facts as to their competitive nature; ultimately these facts will sink in.

Further, to a large extent the products of the natural-resource industries are standardized articles which under normal economic laws are bound to sell at uniform prices at the same time in the same market. No one factor has been more unintelligently used in the attack on trade associations during the last four years than the argument that because prices were uniform at the same time in the same market, therefore such uniformity was the result of combination and of the secret action of trade associations in these industries.

There are not many things on which all economists agree, but if there is one principle as to which there is complete agreement it is that standardized articles will be offered in the same market at the same price by substantially all competitors, and that if a shift in price level is made, whether up or down, by any competitor controlling an important part of the production, there will follow almost simultaneously a similar advance or recession in price by his competitors.

This economic law is merely the expression of economic observation of what takes place in any free market, whether in the market square of an old English town or in the national and international markets of the great standardized products of today. And yet men have been under indictment and tried criminally in the last few years for alleged combinations to control prices, upon no other basis than the fact that their industries were governed by this economic law.

Happily, the Supreme Court of the United States, in a recent case, seems to have recognized the existence of this economic principle in a way which will hereafter be extremely useful to industry in clearing up this fundamental misconception.

#### PHYSICAL DIFFERENCES AFFECT PRODUCTION COST

Finally, there is the significant fact peculiar to natural-resource industries that there results from the actual physical difference in the natural resource a wide difference in the actual operating cost of production. Here is what has happened: The wider margins between operating cost of production and selling price of the physically better mines have frequently been taken as typical of the industry as a whole. Looking merely at these prices, the public clamors that prices are extortionate and the result of combination, when analysis will show them to be normal competitive prices.

A fair test of whether a prevailing market price is a normal competitive price is whether or not a substantial portion of the product is being produced at or about cost. It is obvious that if the price falls below that point, before long a substantial part of production will cease, and the public will not get the material which it needs. If it rises above that point, new producers come into the business and the supply is abnormally increased.

If the facts of any of the natural-resource industries be analyzed for any substantial period of time, it can

be made entirely clear to the public that the prices in those industries are normal competitive prices. If they vary from normality, it will be more often that they are abnormally low than abnormally high.

For example, take soft coal: Last summer we succeeded in prevailing upon the U. S. Coal Commission to analyze the margin between operating production cost and sales price. For the year 1921, in sixty-seven bituminous fields more than 20 per cent of the tonnage was sold, not at or about the cost of production but actually below it; in twenty-one of these fields more than 50 per cent of the coal was so sold.

In a group of mines which had been operating continuously for ten years prior to 1917 and which had thus established their ability to live we found that, during this period, mines producing on an average of 19 per cent of the tonnage sold their product on an average at cost or less.

Those who are familiar with the natural-resource industries are well aware that this situation is not peculiar to the bituminous-coal industry but that an analysis of sales price and cost of all the natural-resource industries would show that a substantial amount of the product which the public requires is produced without margin between cost of production and sales price, or at an actual loss.

The gathering and analysis of figures along these lines can be made absolutely to convince the public that the prices prevailing in natural-resource industries are the normal prices of a highly competitive industry and which must prevail in order to obtain for it the product from them that it requires.

If price fixing were adopted by the government, it follows that price could not be set at a figure lower than that now obtained by competition. It is wholly unfair, therefore, either to take the margins between the operating cost of production and this normal competitive selling price which are obtained by the operators of the physically superior properties as typical of the industry or to denounce the operators of those properties as profiteers by reason of the wider margin they obtain.

#### HIGHER QUALITY ENTITLED TO BETTER PRICE

What is such an operator to do? Is he to sell his product at a price below the competitive market price? Does the producer of wheat on a rich bottom land sell his wheat at a price lower than that of his rival on a difficult upland because he gets more bushels from the acre with less labor cost?

The wider margin of the producer who has a physically superior mine or farm does not indicate that he is making a higher rate of profit, for the rate of profit that he earns is determined by the ratio of his margin between selling price and operating cost to the value of his property. The superior quality of his natural resource, whether it is a farm, a mine or a corner lot, means that it is worth proportionately more, and, ex-

cept in the case of the original appropriator, that he has, therefore, paid more for it.

Some have definitely urged that the government go back to the original expenditure made in the acquisition of any property, whether a mine, city real estate or a farm, and permit merely a return of 6 per cent on that original cost. This proposal is foreign to our whole scheme of economic life. Ownership of mines, farms and city real estate in our economic civilization is constantly changing on the basis of the present value of the property purchased. To restrict the valuation of the investment of the present owners of natural resources, whether land, mines or forests, to the actual expense to the original appropriator in the remote past would mean the taking of property from the present owner without compensation.

Further, there is this practical consideration: The development of our natural resources has been made with the expenditure of an enormous amount of individual initiative, hard work and actual sinking of savings; an enormous amount of this has reaped no reward whatever. It is only the hope of realizing a considerable reward, if successful, that has induced men and women to make the sacrifices they have made in the development of our natural resources. If that incentive for venturing were taken away, the net result to the public would be such a slackening of development of new properties as to result in a diminishing supply and far higher prices.

These facts, the A, B, C of anyone engaged in a

natural-resource industry, are not clear to the public generally, but they are of such a simple and elementary nature that it should be possible to make them clear, and it should be the task of the trade associations, as representative of these industries, to gather the necessary facts and bring them home to the public.

### Coal-Mining Industry Uses 87 per Cent Of Black Powder Output

The production of black blasting powder in 1923 is reported as 8,078,053 kegs, or 201,951,325 lb. This compares with a record production of 11,084,741 kegs, or 277,118,525 lb., of black blasting powder in 1917, according to a report by the Bureau of Mines.

Pennsylvania led in the consumption of black blasting powder, using 39,127,575 lb. Illinois, with a consumption of 37,179,825 lb. ranked second; Indiana, with 21,344,100 lb., was third; Kentucky, with 17,180,175 lb., was fourth; and West Virginia, with 14,817,050 lb., was fifth.

Of the total consumption of permissible explosives, 56,806,709 lb. was used in coal-mining operations, and of high explosives, other than permissible, 37,828,979 lb. was used in coal-mining operations. Of the total black blasting-powder production, 7,019,550 kegs or 175,488,750 lb., constituting approximately 87 per cent of the output, was used in coal-mining operations.

#### A CURE FOR "COAL BARONISM"

The American public probably does not know the story of coal, in spite of much recent publicity. It probably doesn't know that in 1921 20 per cent of the output of sixty-seven coal fields sold at less than cost and in twenty-one fields the proportion was 50 per cent. It doesn't know that a group of mines whose existence was sufficiently justified to keep them running during the ten-year period before 1917 sold 19 per cent of their product at a loss. Facts like these, if properly presented, should quiet the perennial public clamor for lower priced coal, Mr. Dorr thinks, and coal-trade associations ought to do the presenting.

# News Of the Industry

## Ascribe Loomis Blast to Electric Trolley Motors And Cigarette Smoking

*Special Dispatch to Coal Age*

Scranton, Pa., June 27.—State mine inspectors in their report to Joseph J. Walsh, Secretary of Mines, on the explosion at the Loomis colliery of the Glen Alden Coal Co., Hanover township, on June 6, which resulted in fourteen fatalities, ascribe the explosion to the use of electric trolley motors and the failure of employees to observe the anti-smoking regulations.

The inspectors declared they found the electric trolley motors in use in gaseous sections of the mine and discovered cigarette butts and burned match stems in the debris caused by the explosion.

The report by the mine inspectors confirms in part a report made by official investigators for the company who worked with and at the same time as the mine inspectors in seeking the cause of the explosion. The company investigators declared that the explosion was traceable only to the failure of the men to observe the "no-smoking" rule in the mine. This was based on the discovery of burned matches and cigarette butts.

An official of the company, who took a prominent part in the investigation declared that the use of electric trolley motors in the operation could not be ascribed as the cause of the explosion. He pointed out that no electric trolley motor was in operation in the section of the mine affected by the explosion at the time.

Among local coal mining men it is thought that the inclusion of the electric trolley motor as a cause of the explosion may have been written into the report by the mine inspectors to aid Secretary Walsh in his campaign against the use of electrically operated machinery in underground workings. Mr. Walsh has time and again protested against the operation of such equipment as electric trolley motors.

## British Coal Output Nearly At Pre-War Level

Nearly 71,333,000 tons of salable coal was mined in Great Britain in the first quarter of the current year, as compared with 71,667,000 tons in the previous quarter and 70,000,000 tons in the corresponding quarter of 1923, and about 73,000,000 tons in 1913. Shipments of coal abroad, exclusive of shipments to the Irish Free State, according to the Bankers Trust Co., amounted to 19,390,000 tons. This was about

## Democratic Platform's Plank on Mining

The Democratic presidential platform, adopted by the convention at New York June 28, does not contain a separate coal plank like that of the Republican party. The section on mining, which includes coal, is as follows:

"Mining is one of the basic industries of this country. We produce more coal, iron, copper and silver than any other country. The value of our mineral production is second only to agriculture. Mining has suffered like agriculture, and from the same causes. It is the duty of our government to foster this industry and to remove the restrictions that destroy its prosperity."

4,667,000 tons less than in the previous quarter and 2,750,000 tons less than the quantity shipped in the corresponding period of 1913. The quantity available for consumption at home was 49,200,000 tons, or 4,667,000 tons more than the quantity similarly available in the corresponding period of 1923 and 1,500,000 tons more than the quantity available in the first quarter of 1913.

The reduction in the quantity of coal exported was due to a fall in the demand from the Continent, caused in a large measure by the general resumption of work in the mines in the Ruhr coal fields. This substantial decrease in the foreign shipments was not accompanied by a general downward movement in prices. On the contrary, prices on the whole were well maintained and quotations for immediate delivery were higher at the end than at the beginning of the quarter. The mines were worked for 71.29 days out of a possible 78 days.

There was a slight improvement in the regularity of employment in the coal mines. In the first quarter of 1924, 1,206,000 persons, including clerks and salaried persons, were employed in and about the mines, an increase of over 7,000 on the previous quarter and of 89,000 over the number employed at the outbreak of the war. The earnings of workers in the first quarter of the year were rather less on the average than in the previous quarter. However, they were higher than in the first quarter of 1923. There were 310 persons killed and 1,316 persons seriously injured by accidents in and about coal and metalliferous mines. This compares with 313 killed and 1,358 injured in the corresponding quarter of 1923.

## Lease of Norfolk & Western By Pennsylvania Deferred

Lease of the Norfolk & Western R.R. by the Pennsylvania has been deferred, according to a statement by Samuel Rea, president of the Pennsylvania, following the meeting of the board of directors of that road, June 25. "The committee appointed by the Pennsylvania R.R. to consider a lease of the Norfolk & Western," Mr. Rea said, "reported to the directors that it had not reached any satisfactory conclusion on the subject and that further consideration of the matter should be deferred."

This statement followed one by A. C. Needles, president of the Norfolk & Western, the previous day to the effect that the Pennsylvania committee had made no offer for the lease of the property. Both railroads appointed committees to consider the lease, but so far as is known no joint meetings have been held.

First mention of the lease was made by the Pennsylvania to the Interstate Commerce Commission more than a year ago. Officials of the railroad made it clear at that time that the Pennsylvania, which owned a controlling interest in the Norfolk & Western, intended to lease it with the approval of the commission.

According to those in touch with the situation the careful consideration of the problem of leasing the Norfolk & Western convinced some of the members of the board of directors of the Pennsylvania that it would be a costly undertaking. These directors opposed the lease under present conditions. In the New York financial district the opinion was expressed that the announcement made by President Rea was to be taken simply as indicating that the lease would not be given serious consideration until next autumn.

## Sues Union for \$250,000

Mrs. Edna M. C. Major, widow of John I. Major, who was shot to death June 22, 1922, while employed at the Lafferty mine of the Union Coal Striping & Mining Co., filed suit, June 25 in the court at St. Clairsville, Ohio, for \$250,000 damages against the miners' union.

The petition is directed against the United Mine Workers of America, John L. Lewis, president, and William Green, secretary; District No. 6 of the organization, its officers, and Subdistrict No. 5 of District No. 6 and its officers.

According to the petition, Major came to his death at the hands of union miners.

## Peace River Coal Almost Equal to West Virginia's

There is good coal in the Peace River region of northeastern British Columbia—"practically the equal to the high-grade coals of West Virginia and Wales"—according to J. D. Galloway, Canadian Government engineer. Reporting on a long trip of investigation he made several months ago through the territory around what is known as the Peace River Block, he said that the coal is there and mining conditions should be good because of strong roof and floor. All the region needs is transportation and market. The nearest rail line is the westward extension of the Edmonton, Dunvegan & British Columbia R.R., more than 100 miles away. Says he:

"The Rocky Mountain Canyon coal field has been known for many years; leases were taken up in the area by Neil Gething as long ago as 1908. At the present time a syndicate consisting of Neil Gething, George Aylard, and R. F. Green holds forty leases, and another twenty are held by W. S. Johnston. In the immediate vicinity of the canyon no other leases have been taken up, and as the coal is under reserve none can be taken up at the present time. On the Carbon River, thirty miles above the head of the canyon, ten leases are held by C. F. W. Rochfort and partners.

### Strata Notably Regular

"One noteworthy feature of the field is the regularity of the measures. The freedom of the strata from any serious disturbance can be well seen along the canyon, where they extend for miles with almost regular strikes and dips. Dips of from 7 deg. to 15 deg. largely prevail, but in a few places the short limbs of small folds have dips up to 35 deg. Faults are almost entirely absent and the gentle folding of the strata which occurs in a few places is not such as to interfere appreciably with mining operations. It may be safely said that the structural conditions of the measures are such as to make mining operations almost ideal. As a rule the enclosing sandstones and shales above and beneath the coal seams are firm and solid, so that good mining conditions would generally prevail.

"The coal is of high grade. Most of it comes under the classification of semi-bituminous or high carbon coal. Apart from its high-carbon content this coal is noteworthy for its low ash content, which on the average is considerably lower than any of the coals now being mined in western Canada. The high rank of this coal, together with the low ash, makes it altogether an exceptional coal and practically the equal of the high-grade coals of West Virginia and Wales. Most of the coal in this area is non-coking, although certain bands within some seams and certain small seams are fairly good coking coal.

"Two more or less distinct types of coal occur in the field and in many instances a seam will contain a band of each kind of coal. The predominating type, which occurs in far the greater amount, is a hard, firm coal which is

Goldthwaite H. Dorr

Legal adviser of the Bituminous Coal Operators' Special Committee last year, whose address on trade associations, delivered at the annual session of the United States Chamber of Commerce, appears on another page.

dull, grayish and frequently greasy in appearance. This coal would easily stand long transportation without unduly breaking up. The analyses show it to be a high-carbon bituminous coal, with a fixed carbon content of from 70 to 80 per cent.

"The second type of coal is a bright-colored, jet, friable coal, which easily and readily breaks into small fragments. It frequently occurs as a bottom bench, from 6 to 12 in. thick, of a seam containing an upper, generally thicker bench of the dull coal. The jet coal usually is bituminous in rank and it has been found to be excellent blacksmith coal. It has a somewhat higher ratio of volatile combustible matter to fixed carbon than the dull coal and is generally fair coking coal.

"Various estimates of tonnage of coal in the Rocky Mountain Canyon field have been made, but in conclusion, it is enough to say that the tonnage and quality of coal in this field is quite satisfactory and all that is required is transportation and market."

## Coal Towns Safe and Sane

The Pacific Coast Coal Co. is not moved by any diabolical desire to ruin the Fourth of July for the boys of its coal towns. Coal towns will burn, however. Therefore the company has issued orders against all sorts of fireworks and explosives for Fourth of July use. Says a company statement posted at Black Diamond: "A fire might wipe out a town or do such damage that a mine would have to close down, throwing all in camp out of work. At this season of the year, when everything is so dry, the danger of fire is intensified and extra precautions must be taken. It is urgently requested that parents explain to their children why this precaution must be taken."

## Reading Coal Co. Earned \$4,068,694 in 1923

The Philadelphia & Reading Coal & Iron Corporation and its subsidiaries report gross sales of \$89,195,635 for 1923, against \$52,786,120 in 1922. After allowing for all expenses and other deductions, the company reported operating income of \$10,512,976 against \$2,261,415. After crediting other income, and allowing for depletion, taxes and other charges, the company shows net income of \$4,068,694, against a deficit of \$93,430 in 1922. The net income for 1923 was equal to \$2.90 a share earned on the 1,400,000 shares of no par value capital stock outstanding. In his statement to stockholders W. R. Richards, president of the corporation, said in part:

"Total production of anthracite from lands owned, leased and controlled by the Philadelphia & Reading Coal & Iron Co., for the year ended Dec. 31, 1923, was 11,488,513 tons, compared with 6,924,284 tons mined during the previous year. The company mined 10,222,202 tons and sold 9,835,474 tons as compared with 6,100,869 tons mined and 7,398,974 tons sold the previous year. Low tonnage of 1922, both as to production and sales, is attributed to the 1922 strike.

"The funded indebtedness has been reduced by payment of Philadelphia & Reading collateral sinking fund loan of \$30,000. Reforestation of lands is progressing favorably. During the year 225,000 young trees were planted and protective measures for elimination of danger of forest fires are now being carried forward energetically."

## West Virginia Mines Yielded 87,031,408 Tons in 1923

West Virginia coal mines produced 87,031,408 gross tons of coal in 1923, according to figures compiled by the State Department of Mines. The output by counties, compared with 1921 and 1922, was as follows, in gross tons:

County	1921	1922	1923
Barbour.....	1,548,949	817,057	2,149,618
Boone.....	1,475,721	958,912	1,388,562

## Imports of U. S. Coal Exceed British at Rio de Janeiro

Imports of coal at Rio de Janeiro during February, 1924, according to a report by Consul General A. Gauvin, Rio de Janeiro, amounted to 55,351 metric tons, in comparison with 56,513 and 47,640 during the corresponding months of 1923 and 1922. This is the first month since the middle of 1923 that the United States leads in the Brazilian coal imports, 30,567 metric tons having come from that source and 24,784 from Great Britain. The following table shows the coal imports at this port during the first two months of the years 1922, 1923 and 1924, in metric tons:

	1922	1923	1924
United States	13,772		78,468
Great Britain	76,515	109,006	88,919
Totals.....	90,287	109,006	167,387

## Conferences at 19th Hole?

What is believed to be the first golf course for "miners only" has just been established by men at the Powderly colliery of the Hudson Coal Co. in Carbondale, Pa. The course can be used free of charge by all of the 22,000 Hudson Coal Co. miners in the section.

During the month under review the coal imports were classified as follows: 40,768 tons of steam coal, 13,964 tons of gas coal and 619 tons of foundry coke.

Of the coal from the United States, 24,195 tons was shipped from Norfolk and 6,372 tons was loaded at Philadelphia.

## Navy Awards More Contracts

Additional contracts for bituminous coal for navy yards and naval stations during the fiscal year beginning July 1 have been announced by the Bureau of Supplies and Accounts, Navy Department, on the basis of proposals opened May 21, as follows:

Coleman & Co., Inc., Philadelphia, 20,000 tons for delivery at New York at \$5.37 delivered under chutes, \$5.57 delivered alongside vessels and \$6.37 delivered in New York harbor and unloaded.

New England Coal & Coke Co., Boston, 30,000 tons run of mine for delivery at Boston, at \$5.85.

Maryland Coal & Coke Co., Philadelphia, 25,000 tons run of mine for delivery at Philadelphia, at \$4.90.

W. C. Huber & Co., Philadelphia, 35,100 tons run of mine for delivery at Annapolis, at \$5.19.

## Sidelights on the Three-Day Cruise of the Illinois Mining Institute on the Mississippi River

### A Mississippi River Metropolis Where the Illinois Mining Institute Made a Landing

At Grand Tower, near a new gigantic power plant supplying current for many southern Illinois mines, the party went ashore, rode inland 12 miles and visited the plant of the Atlas Powder Co.

### There Are Some Palisades Along the Mississippi

Rock walls 50 ft. high form the west bank of the Father of Waters for several miles below St. Louis, Mo., where the Illinois Mining Institute's boat trip started June 12. Most of the banks are just plain mud, however, on which the shallow-draft steamboats can shove their bows with ease to pick up passengers or freight.

### Parts of "The Gang" Going Aboard After a Stop at Cairo, Ill., World's Hottest Town

When the boat gets under way a gentle wind sweeps from end to end of the meeting room. Moreover the conventions which restrain one in a session in the ballroom of a hotel hamper no one on a river boat, and if perhaps there is less order there is more comfort and a larger degree of bonhomie.

### All Out! End of the Line!

Here we see the Illinois Mining Institute debarking on the old river levee at St. Louis, Mo., Sunday morning, June 15, after three days of cruising down to Paducah, Ky., and back.

### Delay Costs Lehigh Valley Stockholders \$600,000

Holders of 18,000 shares of Lehigh Valley R.R. stock have lost \$600,000 through their failure to exercise within the required time limit their right to subscribe for stock of the Lehigh Valley Coal Co. under the segregation plan of the two corporations, as ordered by the U. S. Supreme Court.

The stockholders were entitled to one share of coal stock at \$1 each for each share of railroad stock owned. The market price of the coal stock is \$34 a share. The railway company mailed out the rights three months ago, fixing the time limit for exchange at 3 P.M. Monday, June 16, 1924. The owners of 18,000 shares failed to execute their rights by that time and this stock now goes to the coal company at \$1 a share.

Since the expiration of the time limit some of the tardy stockholders have sent various excuses to the trustees. The executor of an estate holding 120 rail shares said that he was "away and ill." His delay was said to have cost the estate \$10,560.

### Italy Imports More Coal From the United States

During the first quarter of the current year Italy imported 155,508 tons of coal from the United States against only 160 tons for the same period in 1923 and 50,000 tons in 1922, according to advices to the Department of Commerce from Commercial Attaché McLean, Rome. This increase, despite the relatively small quantity involved, is significant, reflecting the results of persistent efforts on the part of new firms to introduce American coals on the Italian market, Mr. McLean states. The keenness of British competition has been considered by many to be insurmountable, but the figures speak for themselves and of late a number of American coal firms have been showing a growing interest in the possibilities offered by the Italian market.

During the full calendar year 1923 the United States shipped 486,112 tons of coal to Italy against 128,443 tons, in 1922. If exports are maintained for the remainder of the current year at the same rate as during the first quarter the total for 1924 will be 620,000 tons.

Italy's total imports of coal for the first three months of 1924 were slightly below the figures reached in 1923. The following table shows the shipments by the various countries in tons:

#### Italy's Imports of Coal by Countries

Country	First Quarter		
	1924	1923	1922
France.....	123,533	111,295	73,019
Germany.....	123,412	19,533	22,766
Germany (reparation)	298,353	482,372	450,275
Great Britain.....	1,262,334	1,447,179	1,136,112
Jugoslavia.....	3,882	4,287	1,573
United States.....	155,508	160	50,381
Others.....	6,899	3,116	6,231
Totals.....	1,973,921	2,067,942	1,740,357

### Lehigh Valley Coal Miners Abjure Outlaw Strikes

Scranton, Pa., June 30.—Having voted to outlaw petty strikes in the future, miners employed by the Lehigh Valley Coal Co., last night announced their intention of seeking an immediate conference to impress upon officials of the company their desire to observe the conditions of the existing wage agreement.

The menace of petty strikes to which the anthracite industry has been exposed is being eliminated, the spokesman of the general grievance committee of the Lehigh Valley miners declared. He endorsed the action of President John L. Lewis in sending an investigation committee to the hard-coal fields.

During the past week general grievance committees representing the following companies voted to refrain from calling petty "outlaw" strikes: Pennsylvania and Hillside, Glen Alden, Hudson and Lehigh Valley. Under the terms of the promise, the men at operations of these companies will not quit work until they have laid their troubles before accredited union officials, who will then decide whether there has been a violation of the contract by the operators.

The promises were made to the investigating committee which attended all of the meetings of the general grievance committees.

### A. I. M. E. Perfecting Program For Birmingham Meeting

Arrangements for the autumn meeting of the American Institute of Mining and Metallurgical Engineers, at Birmingham, Ala., Oct. 13, 14 and 15, are well under way, the following tentative program having been arranged:

A special train will leave Washington Oct. 7 at midnight for the Shenandoah Valley, stops being made at Luray, the Grottoes of the Shenandoah and Natural Bridge. The evening of the 8th will be spent at Roanoke.

On Oct. 9 the party will breakfast while following the banks of the New River on the way to the Pocahontas coal fields of West Virginia. The day will be taken up with a trip through the field, stops being made at some of the mines and tipples and provision being made for those desiring to go underground. A smoker and dance will be given at Bluefield in the evening.

The morning of Oct. 10 will be spent at the Mascot Mines of the American Zinc Co. of Tennessee, with an opportunity for going underground and to examine the mill and byproducts plant. In the afternoon the party will inspect the marble quarries and mills in the vicinity of Knoxville. The next day, Oct. 11, will be devoted to inspection of the mines, mills, smelters and acid plants at Copperhill and Ducktown.

The first day of the meeting at Birmingham will be devoted to technical sessions, morning, afternoon and evening. The mining of coal and iron in Alabama and the smelting practice of the Birmingham district will be the main topics of discussion, but opportunity will be afforded for the presentation of other subjects.

### Reduction in Insurance For Rock Dusting

State	Per \$100 of Pay-roll, Cents	State	Per \$100 of Pay-roll, Cents
Alabama.....	20	Michigan.....	10
Colorado.....	20	Montana.....	13
Georgia.....	10	New Mexico.....	20
Illinois.....	10	Oklahoma.....	20
Indiana.....	10	Tennessee.....	11
Iowa.....	10	Texas.....	10
Kansas.....	13	Utah.....	14
Kentucky.....	18	Virginia.....	10

If for instance, the rate for a mine has been \$3 and it is located in Alabama, the rate will be reduced to \$2.80 if the mine is properly rock dusted. The saving will be somewhere around \$6 per day. Pennsylvania, Maryland, Ohio and West Virginia, which are state-fund states, are not included in this list. The Inspectors' Committee of the Pennsylvania Rating Bureau has recommended, it is understood, that the deduction be placed at 10c. in that state. The figures have been determined upon the history of mine explosions in the several states.

### Byproduct and Beehive Coke Output Low for May

Production of both byproduct and beehive coke declined during May, due principally to a sharp decrease in the output of pig iron. The quantity of byproduct coke produced was 2,786,000 net tons against 3,010,000 tons in April. Production of beehive coke declined from 1,079,000 to 761,000 tons. In terms of per cent the decrease was sharpest for beehive coke, next for pig iron, and last for byproduct coke. The output for beehive coke fell off 29 per cent, the output of pig iron 19 per cent, and the output of byproduct coke 7 per cent. The average daily production of byproduct coke was 89,855 tons as against 100,326 tons in April, a decrease of 10.4 per cent. Of the 71 plants in existence, 66 were active and 5 were idle. The ratio of production to capacity was 74.5 per cent.

### Monthly Output of Byproducts and Beehive Coke in the United States<sup>a</sup>

	(In thousands of net tons)		
	Byproduct Coke	Beehive Coke	Total
1917 monthly average..	1,870	2,764	4,634
1918 monthly average..	2,166	2,540	4,706
1919 monthly average..	2,095	1,638	3,733
1920 monthly average..	2,565	1,748	4,313

May, 1924.....	4,002	1,200	5,202

## Burns Bros. Earn \$1,305,311 In Fiscal Year

Net profits of Burns Brothers, of New York City, for the fiscal year ended March 31 last, were \$1,305,311 after depreciation and taxes. After allowing for dividends on the preferred stock the balance was equivalent to \$10.30 a share earned on 80,944 no par shares of class "A" common and \$2.30 a share on 80,940 no par shares of class "B" common. This compared with \$1,140,028, or \$9.18 a share, earned the previous year on the "A" stock and \$1.18 on the "B" common.

The company's consolidated income account for last year compared with that of the previous year as follows:

	1924	1923
Net sales	\$30,295,586	\$29,432,807
Cfts. and deposit	27,739,236	26,799,944
Gross profits	\$2,556,350	\$2,632,863
Expenses and taxes	1,581,073	1,909,782
Profit	\$974,577	\$723,081
Other income	330,734	416,947
Net profit	\$1,305,311	\$1,140,028
Pr. pref. dividends	74,935	90,447
New pref. dividends	210,000	210,000
Com. dividends A	809,165	809,159
Com. dividends B	161,757	161,827
Surplus	\$49,454	\$131,405

On March 31 the company had \$2,395,526 cash, \$4,925,318 accounts receivable and coal and supplies on hand valued at \$1,255,952. Accounts payable amounted to \$1,894,975.

At the annual meeting of the board, June 12, Charles Hayden, of Hayden, Stone & Co.; William J. Wason, vice president of the Kings County Trust Co., and Alfred T. Holley, coal and feed dealer of Hackensack, N. J., were elected directors of Burns Brothers to fill two vacancies and that created by the retirement of C. R. Runyon. The other directors were re-elected.

## Maps of Superpower Survey Soon Available

The seventeen plates prepared by the Federal Power Commission in connection with the superpower negotiations being conducted by Secretary Hoover are now in the hands of the lithographers. Copies will be available for distribution soon.

The plates being made of maps and curves will be accompanied by a short text, setting forth the findings and conclusions of the engineers who assembled the data. The growth of population and of power consumption in each of the states covered and for the entire eastern section of the northeastern area will be shown. Generating capacity, power loads, hydro-electric possibilities, transmission lines and coal deposits will be shown.

The information set forth in these lithographs will be of particular value to everyone interested in power since it concentrates in graphic form information from several federal agencies and from the states included in this survey.

The fifteen states included in the survey produce half the country's output of power.

A. C. Fieldner

Superintendent of the Pittsburgh station of the U. S. Bureau of Mines, who sailed June 19 for London to attend the world power conference.

## Coal Output of Russian Mines Exceeds Program

Gross output of coal by all the coal trusts of Russia during the first six months of the fiscal year 1923-24 (Oct. 1, 1923, to April 1, 1924), according to the *Russian Review*, totaled 362,178,000 poods (a pood is equal to 36.113 lb.), which is 11 per cent in excess of the program and 44.8 per cent more than the output for the corresponding period of the previous year. Of this amount, 69,100,000 poods, or 17 per cent of the output, was used for the needs of the trusts, which is considerably less than the amount used for the same purpose last year.

Shipments from the mines totaled 203,000,000 poods, compared with 187,800,000 poods last year. The increase in shipments, however, is not in proportion to the output, for supplies at the mines were estimated on April 1, 1924, at 1,919,900,000 poods.

## Germany Protests Against French Troops in Sarre

Germany has lodged a protest with the League of Nations against the French military occupation of the Sarre coal field, in which France was given exclusive mining rights for fifteen years by the Treaty of Versailles. The Teuton government complains that the continued presence of French troops will exercise an unfortunate moral influence upon the plebiscite which will decide the future of the Sarre territory at the end of the fifteen-year period. Germany requests that the French occupation be brought to an end and that a local gendarmerie be constituted to take the place of the French forces on police duty.

The Council of the League of Nations, in session at Geneva, Switzerland, June 11, postponed action on the note until the August session, but it adopted a resolution expressing satisfaction with the Sarre Governing Commission for increasing the gendarmerie in compliance with the wishes of the council.

## Docks Get Little Coal in First Part of Summer

Although movement of coal to the Northwest by the Lakes picked up noticeably after the Interstate Commerce Commission made its recent Northwest rate decision favoring dock shippers, the amount of coal put on the Duluth-Superior docks up to June 1 was only a little over half that of the corresponding period in 1923. Total soft-coal receipts to May 31 were but 996,161 tons this year as compared with 1,832,344 tons last year. Hard-coal receipts were 41,084 tons less than in the same period of 1923 and soft-coal receipts 795,099 tons less, as indicated in the following tables of comparative receipts:

### HARD COAL

	Net Tons
April, 1924	84,392
May, 1924	80,240
Total to May 31, 1924	164,632
Total to May 31, 1923	205,716

### SOFT COAL

April, 1924	240,018
May, 1924	591,511
Total May 31, 1924	831,529
Total May 31, 1923	1,626,628

### TOTAL HARD AND SOFT COAL

April, 1924	324,410
May, 1924	671,751
Total May 31, 1924	996,161
Total May 31, 1923	1,832,344

## Austrian Coal Output Gains

Austrian coal production in January, 1924, according to a report from Assistant Trade Commissioner Prentiss M. Terry, Vienna, amounted to 15,662 tons of pit coal and 275,533 tons of lignite, a total of 291,195 tons, as compared with 14,014 tons of pit coal and 239,673 tons of lignite in December, 1923, a gain of 14.8 per cent.

The 291,000 tons of coal produced in January, 1924, exceeded the average monthly production of 1923, which amounted to 234,700 tons, by 56,000 tons or 24 per cent.

Output of Austria in 1923, by provinces, together with the January, 1924, output and the share of each province in the increased production was as follows, in metric tons:

State	Year 1923	Jan., 1924	Increased Output Over 1923 Monthly Average
Styria	1,575,047	161,925	30,000
Upper Austria	355,297	43,167	14,000
Lower Austria	329,221	32,254	4,000
Burgenland	435,577	39,975	4,000
Tyrol	36,912	2,710	
Carinthia	85,037	11,164	4,000
Total	2,817,091	291,195	56,000

Imports into Austria during 1923 totaled 3,755,210 tons of pit coal; 865,010 tons of lignite and 403,176 tons of coke.

Total Austrian consumption of mineral fuel in 1923 amounted to 7,814,780 tons as compared with 9,084,945 tons in 1922, a falling off of 1,270,165 tons or 14 per cent. Of the total consumed, 2,791,384 tons, or 36 per cent, was produced by domestic mines and 64 per cent was imported.

## Discussion

### Did Mine Inspectors Demand Too Little?

More Inspectors Needed—Every Mine Should Be Treated as Gaseous—  
Mechanical Inspectors Should Examine Equipment  
Every Thirty Days

AN ARTICLE in *Coal Age*, May 29, 1924, entitled "Mine Inspectors' Institute Advocates Legislation, etc." contains a list of the demands in the interest of safety.

These demands are good, but the inspectors might have added some more of great importance if their purpose had been to give a complete review of present safety needs in coal mines, as anyone will realize who is familiar with the history of coal mines in America and considers the many fatal mine explosions and mine fires that have occurred, some of them quite recently. If the article as it appeared in *Coal Age* is a complete record of the inspectors' deliberations at the institute it seems that some one must have clapped a muzzle on them. Here are a few regulations that should be considered:

(1) Prohibit the granting of second-grade certificates for mine foremen. (2) All mines should be considered gaseous and be examined prior to the entry of miners. (3) The use of electric haulage motors should be prohibited in pillars. (4) Exhaust ventilation should be provided in all mines. (5) Electric hoists should be prohibited in rooms and pillars. (6) No electric

hoists should be permitted in entries except on intake airways and all should be of the explosion-proof type and set at least 100 ft. outby from the last crosscut. The rope should not be allowed to come in contact with any metal or steel that would cause an arc. (7) All pillars should be ventilated by a separate split and no return should be allowed to travel into other live entries or pillars. (8) Where force fans are used drill holes should be put down from the surface to all pillar sections.

(9) Escape and ventilation shafts or slopes should be provided in all mines driven a distance of one mile or more from the nearest entry. (10) All electric apparatus should be of the explosion-proof type and operated and installed only in intake airways. (11) Inspectors should be equally responsible with the mine management for the enforcement of safety in and about all coal mines. (12) At least one full crew of first-aid and mine-rescue men should be provided at every mine. (13) A mechanical inspector should examine all machinery in and about coal mines at least once every three months. (14) Enough mine inspectors should be provided to allow every mine to be examined at least once every sixty days. Du Bois, Pa. ALFRED ENGELL.

### Two Provinces Seek to Fill Canada's Coal Bins

I have read with interest a reading notice that appeared in the *Montreal Star* on Monday. It quoted from an article by M. D. Geddes as published in *Coal Age*. This article dilated on the coal resources of Canada and the possibility of the United States discontinuing the shipment of anthracite across the international line.

Mr. Geddes referred specially to Alberta and dilated on the tremendous quantity of coal available in that province. However, for some time at least, it will not be practicable to bring that coal to Ontario and Quebec, and Ontario particularly is the point which suffers from its dependence on United States coal. We are inclined to think that the first relief will come from Nova Scotia and that coal will be shipped by water to Montreal and possibly, pending the enlargement of the canals, trans-shipped to smaller vessels and on to Ontario.

Though the coal in Nova Scotia is all bituminous, some of it is of the highest quality. In business the practice is to take the course of least resistance and it seems to me that the

first thing for Canada to do would be to use Nova Scotia coal so far as possible. Some day in the near future large coking plants will be erected at Montreal and Toronto where Nova Scotia coal will be turned into coke and thus a fuel that will supplant anthracite will be available.

W. A. MACKENZIE,  
President.

W. A. Mackenzie & Co., Ltd.,  
Toronto, Can.

### Here Is a Difficult Problem

At the mine we are working, the coal is of splint structure with the following average section: hard slate top, drawslate, 10 in.; fine grade of coal, 48 in.; soft slate, 4½ in.; coal, 4½ in.; mixed slate and coal, 5½ in.; coal, 11 in.; sandstone bottom. The soft slate immediately underlying the 48 in. of coal will not support the weight of an undercutting machine of the shortwall type without the aid of steel skids. It is also so soft that a loader cannot be permitted to use his shovel on the bottom. Can any reader of *Coal Age* suggest a suitable method of operation?

WEST VIRGINIA OPERATOR.

### Old Men More Subject Than Younger to Accidents

In the article "Old Men More Subject Than Younger to Accidents" in the issue of June 26, 1924, my meaning and that of T. T. Read has been misinterpreted. In the 28th line, second column, "accidents away from the mines" has been written "accidents in other industries" instead of "non-occupational accidents among miners." Similarly "Other Accidents" should read "Non Occupational Fatalities of Miners" and not "Fatalities of Others." In some other places the same misinterpretation occurs. The figures from the report of the Registrar General, Great Britain, should be used in every case to compare the fatalities of miners at the mines and away from the mines with each other and by wage groups "Frequently" on line 37, col. 1, should read "Frequency" and "about" on line 19, col. 2, should read "above." The figure 8 in the fourth column of the table though out of line with the other figures is correctly quoted.

W. W. ADAMS,  
Statistician.

U. S. Bureau of Mines,  
Washington, D. C.

### Saves One-Third of Powder, Not Two-Thirds

An error for which the editor is not to blame appears in my paper on "Increasing Lump Coal Production by Cushioned Blasting," published in your issue of May 29. On page 805, second column, line 11, the figure given should be two-thirds instead of one-third. The whole sentence which refers to the tests made with rock-dust stemming at an Illinois coal mine should, therefore, read as follows: "The shots made by this method with about two-thirds of the original powder charge brought down the coal satisfactorily with appreciably less screenings than are generally obtained."

J. H. HORLICK, JR.,  
Manager service division,  
Hercules Powder Co.

Wilmington, Del.

### Queer Mine Names

Speaking of queer mine names, I recall those of two little mines that were operated a few years ago when I was district mine inspector, which I believe will compete favorably with the "Struggling Monkey" mine, mentioned in the item that appeared in *Coal Age* Dec. 27, p. 968; or the "Toadvine," or "Who'd 'a' Thought," in the issue of Jan. 24, p. 151, and are entitled to a place in the front ranks of the list of queer mine names.

The first is a little mine operated by the Dayton Coal & Iron Co. on its branch line two miles north of Dayton. It was called the "Tickle Gizzard" mine. Another little mine, located in Scott County and operated by the Paint Rock Coal Co., went under the name of the "Possum Jaw" mine.

JOHN ROSE.

Dayton, Tenn.

## Practical Pointers For Electrical And Mechanical Men

### How to Use Grinding and Polishing Wheels

The Whole Peripheral Surface of the Wheel  
Should Be Used—Ways to True Up the Wheel  
—Putting a New Face on the Polisher

BY GUSTAV RADEBAUGH  
Urbana, Ill.

EVERY grinding stand should be provided with a safety hood and with a grinding rest that can be adjusted readily. It is important that the grinding rest be adjusted so as to be close to the wheel at all times. In many grinding operations the job is often of such size that it can easily be caught between the rest and the wheel and cause injury to the operator. The grinding rest and hood shown in Fig. 1 gives a good example of a well-protected wheel. When grinding, the top of the wheel should always turn towards the operative, and the work should be moved over its entire face. Often on the inspection of a grinding wheel it will be found that the face is uneven, which makes it difficult to do good work. This is caused by holding the material being ground steadily in one position. One of the most common improper practices is grinding a rod as shown in Fig. 2.

In cutting threads on rods the die will start more easily if the end of the stock is pointed to receive the die. The easiest way to do this is on the grinding wheel. There is no need, however, for wearing the wheel unevenly, if the rod is moved across the face as previously explained. Never hack or gouge a wheel, for in so doing it may be cracked to such an extent that it will break when in service.

When the wheel does not cut as freely as it should and the work heats quickly, the wheel probably needs dressing. This can be done with the grinding-wheel dresser. It is well

Fig. 1—Adjusting the Rest

If there is much space between the wheel and the rest material will easily get jammed, endanger the operative and probably break the wheel.

Fig. 2—Tapering a Rod

Unless the whole working surface of the wheel is used uniformly frequent truing will be necessary. Always move the material being ground across the face of the wheel.

to have a dresser always at hand and ready for use, because it is of utmost importance to keep the wheel sharp and perfectly true. One style of dresser is shown in Fig. 3.

I have found that a more accurate job can be done if the dresser is held in such a position as to bring the lugs on the bottom of the dresser against the grinding rest. If the wheel is running out of true, two definite centers having been established, the dresser being held in this manner the high spots will be removed. It is evident that if the dresser is not held immobile the wheel will not be properly dressed, for the dresser then will follow the peripheral shape of the wheel instead of correcting it.

If a commercial dresser is not available a good dresser can be made with a steel handle supporting five or six  $\frac{1}{8}$ -in. washers on a bolt. This improvised dresser is not the best for truing a wheel but it will sharpen it satisfactorily. If too much dressing is necessary it is an indication that the wheel is too hard for the work or that it is being run at too high a speed. If the proper grade of wheel is used it should run at a peripheral speed of 4,000 to 6,000 ft. per minute. Referring to the table, the diameter of the wheels and the revolutions per minute of the spindle are listed which give peripheral speeds of 4,000, 5,000 and 6,000 ft. per minute.

When grinding very soft metals, such as lead, aluminum, or brass, the wheel, if not specially made to cut

Table of Grinding-Wheel Speeds

Diameter Wheel Inches	Peripheral Speeds		
	4,000 f.p.m. Expressed in r.p.m.	5,000 f.p.m. Expressed in r.p.m.	6,000 f.p.m. Expressed in r.p.m.
4	3,820	4,775	5,730
6	2,546	3,183	3,820
8	1,910	2,387	2,865
10	1,528	1,910	2,292
12	1,273	1,592	1,910
14	1,091	1,365	1,637
16	955	1,194	1,432

these soft metals, will become "loaded" and will not cut. A wheel is said to be loaded when the pores of the wheels are partly or entirely clogged with the material being ground. This prevents the wheel from cutting and causes excessive heating. If the wheel is loaded the surface will show it plainly. This is caused by the wheel being too hard or the speed too slow or of improper grain and bond. To overcome this, increase the speed or use a softer wheel.

#### POLISHING AND BUFFING WHEELS

Polishing and buffing wheels made from sheepskin, canvas and wood are only a few of the soft wheels used for polishing and buffing. These wheels are revolved on the grinding stand at a little higher speed than the grinding wheel. The manufacturers of these soft wheels recommend that they be run at a peripheral speed of 7,500 ft. per minute. Every mine repair shop should be supplied with one or more soft wheels.

Such wheels can be resharpened by applying new abrasive material. This is done by applying glue as shown in Fig. 4. After a good heavy coat of glue is placed on the wheel it is rolled in a box, as shown in Fig. 5, which contains abrasive material. It will pay to make up a neat substantial box for this purpose as it is essential that the surface on which the abrasive material is placed be true and close grained.

Fig. 3—A Dressing Tool

This device is used to straighten the cutting surface of the wheel. By holding the dresser on the rest the work can be done with greater accuracy.

Fig. 4—Applying Glue to Wheel

When polishing wheels become dull and fail to smooth the surfaces exposed to their rotating action, glue is applied to them to hold new abrasive material.

It is always well when rolling the wheel to apply considerable pressure because this has a tendency to force the grinding crystals well into the glue. After the wheel has been well rolled and the abrasive crystals cover the entire face, it is good practice to roll the wheel over a smooth board applying considerable pressure on the wheel. This will even up the face and

Fig. 5—Roll Wheel in Abrasive

A box is constructed of close grained wood with a smooth bottom. The bottom of this box is dusted with abrasive, and the wheel just glued is rolled in the dust under pressure.

cause the crystals to hold more firmly on the wheel when in use.

The abrasive crystals for soft wheels can be purchased in cans containing from  $\frac{1}{2}$  lb. up to 10 and 20 lb. The most common sizes for polishing range from 20 to 80 grain. There are few jobs in general repair work requiring any finer grade than No. 80. Grain sizes of abrasives between 20 and 80 are 24, 30, 36, 40, 46, 54, 60 and 70. The

Fig. 6—Placing Wheel for Drying

It is essential that the abrasive be untouched for several hours, so that the glue may be enabled to harden and hold the abrasive particles. This should be done in a dry, warm room. This illustration shows one way in which this drying can be arranged.

20 grade is the coarse, the 80 the fine. Finer grades such as 90, 100, 120, 150, 180 and 200 are used to prepare work for a high polish.

Once thoroughly rolled the wheel is then laid away to dry before it is used. It should be permitted to season in a warm, dry room for several hours. It is important that the face of the wheel should not come in contact with any object as there is danger of injury to the grinding face. One method of placing the wheel for drying is shown in Fig. 6.

## Electric Heaters Dry Out Motors and Conduits

In any mine where water has to be pumped or, for that matter, on the surface also, floods may occur and drown the electrical equipment, perhaps, especially in the case of pump motors, just when the need for the use of that machinery is greatest. At such time an oven is needed for drying out the coils. This oven should be of a certain easily regulated temperature, equal both night and day and in all parts of the oven. It should do its work without attendance and should be free from deleterious fumes of any kind.

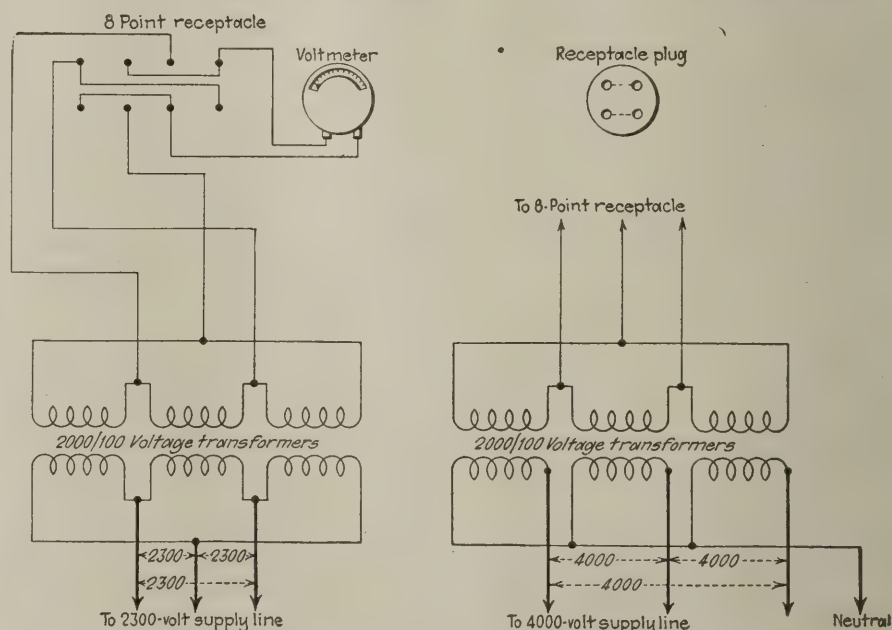

The electric oven or electric heater even without the oven is the most practical and efficacious way of drying wet electric apparatus as was well illustrated when a flood occurred above Cumberland, Md., spreading some 40 or 45 miles west of that city and flooding the streets of Piedmont, W. Va., 3 or 4 ft. deep.

As soon as the flood had subsided ways and means of drying out the water-soaked electrical apparatus were considered and a decision was made in favor of electric heat as the quickest

and most convenient way of driving out the moisture. Accordingly fifty 2½-kw. oven heaters were immediately shipped to the inundated area. When the heaters arrived, a temporary oven was built and fifteen heaters were arranged in three banks of five each and connected to a 550-volt trolley line. The owners brought their electrical equipment to this oven for treatment. The mud and *débris* were washed off with a hose, and the motors were placed in the oven to be dried. Insulation checks were made with a "megger," and when the parts were considered dry they were cleaned and sprayed with insulating varnish and returned to the factories.

In some instances, it was possible to dry the motors in place, merely by placing the heaters around the equipment and covering them. A great many conduits were dried by placing the heaters underneath the conduits and letting the warm air pass through them. Whenever the heaters could be placed close to the conduit, no wires had to be drawn and the circuits tested out perfectly after drying.

At one plant, over 300 motors, ranging from 1 to 400 hp. were under water. One hundred heaters were sent to the plant and the motors were dried out in place. In less than two weeks, the entire equipment of the plant was again in operation, and less than one per cent of the motors required rewinding or repairing. In this plant, the heaters were simply placed right up against the motors in such a way that an even drying heat could be obtained. It was unnecessary to disconnect the motors or to place them in an oven for drying. A little consideration of the conditions at the mines will enable the reader to adopt for his own use the methods put in operation after the flood just described.

Simple Connection Diagram for Three-Phase Voltmeter Circuit

The best way to prevent delays and breakdowns is to keep a constant check on the performance of equipment. The most essential detail is proper operating voltage. Many three-phase motor circuits are provided with voltmeters, but frequently the meter is connected to but one phase. Sometimes the meter conveys the idea that the voltage is of sufficient value because it is permanently connected to a good phase. Usually the control- or power-distributing circuit is provided with three voltage transformers and it is a simple matter to connect an 8-point receptacle so that the voltage of each phase may be read independently. The diagram shows the connections which may be used for this purpose. The circuit on the left shows delta-connected 2,300-volt transformers. On the right the same type of transformers are connected wye to a 4,000-volt circuit.

# Production And the Market

## Bituminous-Coal Trade Optimistic While Waiting For Business to "Turn the Corner"

While the bituminous-coal market exhibits no haste in getting "around the corner" from the depression that has held the business in its grip for so long, a fair degree of optimism prevails, born of quiet confidence that awaited developments for the better are about to materialize. Already foreign charters for July at Baltimore are reported at a rate that augurs well for late summer and autumn export business. In most other aspects, however, there is little evidence of actual improvement, additional financial reports by coal-carrying railroads reflecting the adverse effect of the decrease in shipments of soft coal. This is especially marked in the case of the Virginian.

### Navy Department Places Contracts

The Navy Department has awarded contracts for 110,100 tons of mine-run bituminous coal for navy yards and naval stations, on the basis of bids opened May 21. Twenty thousand tons will be delivered at New York at \$5.37 per ton under chutes, \$5.37 alongside vessels and \$6.37 delivered in the harbor and unloaded; 30,000 tons will be delivered at Boston at \$5.85 per ton; 20,000 tons at Philadelphia at \$4.90 per ton, and 35,100 tons at Annapolis at \$5.19 per ton.

As in recent weeks, *Coal Age* Index of spot prices of bituminous coal shows no variation, standing at 166 on June 30, the corresponding price being \$2.01. This is the third successive week that it has remained at that level, which would seem to bear out the theory that the bottom has about been reached.

Activity at Hampton Roads has slumped to a marked degree, dumpings of coal for all accounts during the week ended June 28 totaling 287,870 net tons, a falling off of more than 60,000 tons from the week ended June 21, when 350,821 tons was handled. Coal dumped at Lake Erie ports during the week ended June 21, according to the Ore & Coal Exchange, was as follows: Cargo,

699,519 net tons; fuel 41,168 tons. The figures for the preceding week were 645,978 net tons of cargo coal and 39,184 tons of fuel coal.

Production of bituminous coal advanced slightly during the week ended June 21, but was still below that of the week ended June 7, when the more marked increase was due to a post-holiday spurt. The output for the week ended June 21, according to the Geological Survey, was 7,218,000 net tons, a gain of 66,000 tons over the revised figures for the preceding week, when 7,152,000 tons was produced. Anthracite production

was unchanged, the output for the week ended June 21 being 1,823,000 net tons, the same as for the previous week.

The slowing-down tendency in anthracite business is still in evidence, the market apparently having fallen into the throes of a summer lull that is likely to last until late-summer or early-autumn ordering sets in. Although July price advances were looked for, independent quotations show a weakening, due to the scarcity of orders. Stove continues to lead in demand, with no close competitor among the other sizes. Pea is lagging to such an extent that it is being stored. The demand for the buckwheats is fading fast.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
June 7	10,676,000	7,373,000
June 14 (a)	10,573,000	7,152,000
June 21 (b)	10,422,000	7,218,000
Daily average	1,737,000	1,203,000
Cal. yr. to date	260,353,000	218,861,000
Daily average to date	1,771,000	1,490,000

#### ANTHRACITE

June 7	2,046,000	1,846,000
June 14	2,053,000	1,823,000
June 21	2,042,000	1,823,000
Cal. yr. to date	49,287,000	43,707,000

#### COKE

June 14 (a)	406,000	131,000
June 21 (b)	398,000	128,000
Cal. yr. to date (c)	9,603,000	5,955,000

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### No Midwest Pick-Up Yet

Not a bit of improvement in the markets of the Midwest region was noted during the week. The domestic market for lump is simply non-existent. Practically all lump coal is being crushed. A very little 6 x 3-in. egg is produced for the benefit of the few dealers who are beginning to stock a little, having concluded that the price will never be lower, but day-to-day steam business is all that is worth talking about. Screenings and the smaller nut sizes are moving, although sluggishly. A little good southern Illinois screenings going to the country still brings as high as \$1.90, but that which goes into Chicago sells for \$1.75@ \$1.85. Central Illinois screenings are a little firmer at \$1.60@ \$1.75.

Western Kentucky coal continues to disturb the Midwest market for all other coals. Mine run at \$1.40@ \$1.60 and screenings for a short time ranging from \$1.25 upward set price paces that cannot be met. St. Bernard coal from mines that are trying to open on a 1917 wage basis has not yet appeared on the market. A July price of \$2 on smokeless mine run has been announced in Chicago. The market for this coal is very draggy just now. There are practically no new contracts on any kind of fuel.

A survey of the retail situation at St. Louis develops

the fact that domestic coal has not been put in this spring by the more prosperous homes for one principal reason: wet weather. People who have soft drives and whose coal is hauled across the lawn will not consider putting it in until the ground hardens up, and in this territory there has been rain every day for over two months. Practically no storage coal is being handled and coke also has dropped off. Wagonload steam is almost at a standstill and country domestic is absolutely dead. Local carload steam is quiet, although the big plants are buying a little and country steam is not a factor.

There has been no change in St. Louis prices. In anticipation of better business the next two months something like 2,000 tons of smokeless West Virginia has been ordered for July and August shipment. These orders were placed last week. Dealers report heavy supplies of all higher priced coals on hand in anticipation of some demand in July.

### Kentucky Feels Better

Business is showing just a little improvement with the Kentucky operators, and the outlook is better than it has been for some time past in spite of dullness in the iron, steel and the auto industry and a slowing down of small industries in various lines. The eastern Kentucky field, aided by low wage scales as compared with the union fields, has

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	June 30	June 23	June 16	July 2
Index .....	166	166	166	203
Weighted average price .....	\$2.01	\$2.01	\$2.01	\$2.46

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

been able to operate 50 per cent or better. In western Kentucky the strip mines are reported to be operating six days a week in some instances, and to be loading out a lot of coal. Indications also are for larger production in that field as a result of a couple of companies having been able to resume operations on a reduction of 20 per cent in wage scales.

Retailers are meeting with a slightly better stocking demand from domestic consumers, resulting in somewhat better call for mine run and prepared sizes, while screenings, although in better supply, have been moving a shade more briskly as a result of some large consumers exhausting their storage stocks. School and institution contracting is improving. Lake movement has been slow in developing, but is coming better. Utilities and big industrial consumers have adopted a waiting policy in spite of low prices. Prices continue steady except that screenings are slightly weaker, due to larger production.

### Northwest Markets Lifeless

The Milwaukee market is lifeless, with little prospect of betterment during the summer months. Bituminous coal, especially the inferior grades, is weak and somewhat unstable in price. On the other hand, Pocahontas egg and nut have been advanced 50c. per ton. The price is now \$9.25 wholesale and \$10.75 retail. Cargo receipts since the opening of navigation aggregate 242,598 tons of anthracite and 523,420 tons of soft coal. Anthracite is short 25 per cent and bituminous about 50 per cent compared with this time last year.

Competing desperately for business and getting but little result is the present story of the coal trade in the Minne-

apolis and St. Paul territory. All concerned are mixing in a free-for-all in which no holds are barred and no rules apply. For instance, a contract for 1,200 tons of Youghiogheny lump was bid for a North Dakota town at \$4.90, a cut of \$1.10 from the list price. But even price slashing gets little business. The anticipated trade resulting from July 1 exhausting of stocks is not developing. Several of the railroads are feeling around on the subject of contracts for the coming year, but as they are covered for 60 to 90 days, they are not eager.

The dock companies are receiving fair tonnages for their Lake Superior docks, but seem not inclined to load them as heavily as a year ago, even with the promise of better related freight rates with which to meet all-rail competition. Prices on all-rail coal continues to be low. Franklin County (Illinois) lump continues to be around \$2.50, with little response to this figure.

### Parts of West Do Business

There has been no change in conditions in the Southwestern district as compared with those of a week ago. A little storage of Arkansas semi-anthracite by home owners is reflected in increased orders from retailers, there has been a slight increase in the demand for Kansas coal for threshing as the harvest starts, and the industrial demand for screenings continues sufficiently strong to prevent accumulation of "no bills." Prices are: Kansas lump, \$4.50; nut, \$4; mine run, \$3.50, and screenings, \$2.50. Arkansas semi-anthracite lump, \$5.50@6; mine run, \$3.25@3.50, screenings, \$2. Henryetta (Okla.) lump, \$5.50; nut, \$3.75; mine run, \$3.50; screenings, \$2.50.

The coal market in Colorado dragged along during the past week without much change. Dealers still remain indifferent as to summer orders, despite the fact that another advance in price was scheduled for July 1. Colorado mines averaged 21 hours last week. Forty-six per cent of working time lost was attributed to no market.

Utah mines are increasing production slightly. The working time is now fully two days a week. There are fewer "no bills," but there are still too many for the good of the industry and the railroads. Operators report lump coal to be a drug on the market, but in some cases they are finding it hard to supply the trade with smaller sizes. The slack situation is satisfactory. In spite of the efforts of organized retailers, very little coal is being stored yet.

Further gains have been recorded in the production of mines in southern West Virginia, the output of mines in the northern part of the state remaining about the same. Although some smokeless contracts have been made recently, many sales are on a spot basis and the spot market is far from brisk. So far as high volatile is concerned there has been little change in price or demand.

### Domestic Trade Stronger in Ohio

Smokeless domestic coals are stronger in the Cincinnati market because of a further limitation of production. Low-volatile operations are closing down because of the apparently hopeless situation as to slack, which had dropped to \$1 and \$1.25 this week in the best byproduct production, without any visible stimulation of demand. High-volatile coals are all off, nut and slack being weaker. Steam demand has fallen off in part at least because industrial operations have been reduced by shortage of orders. Domestic demand is better and further improvement is expected to follow the customary beginning of household buying for next winter's use in July. The state government will call for bids within a few days on 150,000 tons of coal for state institutions.

The small increase in demand for domestic sizes at Columbus continues, but steam trade is rather dull and featureless. Utilities and railroads are the best purchasers of steam grades while school coal also is moving freely. There is not as much distress coal on the market and prices are steadier. Contracting is slow as most of the consumers are buying from the open market.

Smokeless, which was fairly active several weeks ago, has relapsed into quietude. Splints and Kentucky grades are the best features of the domestic demand. Retail prices are fairly steady at the levels which have maintained for some time. Little demand has developed for Ohio-mined varieties. Lake trade is not cutting much figure as far as the southern Ohio field is concerned, but in eastern Ohio there is a considerable lake movement, which is holding up the output.

Stagnation prevails in the Cleveland market. Some of the larger operators feel that the turning point is not far distant, however, and are taking hope. Stocks can last but a short while longer. According to a monthly survey of coal consumption made by the Fuel Committee of the National Association of Purchasing Agents, coal consumption during May of this year was nearly 25 per cent less than in May, 1923.

The Pittsburgh market shows no discernible change for the week. Slack seems to be a trifle easier but can hardly be quoted any lower. There are no signs of the district being able to work in the lake trade to any extent, while the steel industry has slowed down farther and some mills will close next week for a week or more, so that demand is likely to be lighter before it is heavier.

Production in central Pennsylvania remains stationary. The scramble for orders makes it possible for some mines to do business, but others, unable to get orders, must close.

Trade at Buffalo is about as dull as it ever is at this time of the year. Some of this inactivity is due to the slowing down of business during the past few weeks, a state of things that it expected to continue until there is less politics in the air. This means till fall, no doubt.

### New England Market Drags

In New England the market drags along with little relief from the dullness that has prevailed for so long. The price of \$1.50 per net ton at the mines for slack, recently made the Panama R.R. by one of the smokeless agencies, is a fair indication of the state of trade, and while there are some who persist in being hopeful and are sure that before many weeks now the corner will have been turned, the general opinion is none too favorable. While accumulations at Hampton Roads are not as large as at times there is a plenty on hand for spot dumping. The range of price is precisely the same as a week ago, namely: \$4.25@ \$4.40 per gross ton f.o.b. vessel.

For distribution inland there is a similar lack of interest on the part of buyers. The nominal quotation at Boston still is \$5.75 per gross ton on cars, but sales are still reported at \$5.50@ \$5.60. At Portland the range is perhaps 15c. higher, but inquiry is fugitive.

All-rail from central Pennsylvania the state of things is most discouraging. A slight indication of better prospects a week ago has given way to a rather hopeless attitude so far as concerns July business. Even small consumers who buy but a few cars each summer are postponing their purchases, being led to think the current market holds no inducement.

Trade at the New York and Philadelphia piers is extremely dull. Movement for coastwise delivery is very light and prices are depressed.

### Buying Limited in Seaboard Markets

Buying is scarce at New York, although the daily average of cars reported at the tidewater terminals remains around 1,500. Tidewater quotations have, however, not been affected to any extent although occasional purchases are reported at less than the printed quotations. Line demand is slow and easy. Things look brighter to those salesmen who travel New England territory and more inquiries are reported from buyers. In the New York market the tendency of consumers with reserve stocks to reduce them before placing new orders continues. Few if any contracts are reported as being made.

The Philadelphia market is soggy, buying being on a limited scale. Efforts to induce the iron trade to take in

excess coal, as it usually does at this time, are unavailing. Central station power plants are buying liberally. The railroads still have goodly reserves on hand. Spot prices are unchanged and tide conditions have not improved.

Industrial demand at Baltimore continues light and while there is a feeling in the air that a change for the better is about due and that business generally has been dragging bottom and will now come up on a flood tide, there is no actual indication of this as yet. The coal roads continue to report light haulage and mine representatives and jobbers say that selling has to be forced at all times. The fact that exports have shown up a bit better for the middle part of June, and that a number of charters are reported ahead for July, has heartened that end of the business.

General depression rules in the Birmingham markets, with scarcely an inquiry. Consumers are apathetic, as all branches of industry are slowing down and fuel requirements are essentially being decreased in a comparative degree. Domestic grades will be up about 20c. per ton in July over the June schedules. Several commercial mines holding old contracts with the Seaboard Air Line which were not renewed for the coming year, are closing down.

### Anthracite Market Continues to Slip

Demand for anthracite continues to slacken and quotations for independent product are a trifle lower, unless straight lots of stove coal are desired. On July 1 the larger producers, including independent operators, were expected to issue new prices showing advances from those announced on June 1 for domestic sizes, although there was some talk that the independent operators might not make any advances because of the present lack of demand. No heavy buying of domestic coals is expected until the vacation season is about ended. As during the past several weeks, stove coal is leading the demand and most dealers find it necessary to take either egg or chestnut in order to get the former. Pea coal continues to lag and storing is being resorted to. The demand for the buckwheats is rapidly disappearing.

Summer weather has put almost an entire stop to the retail trade in Philadelphia. The yards are well stocked with all sizes except stove, and even this size is coming along more freely now than at any time since spring. Stocks of chestnut coal are larger now than for years, and most of the dealers have no room for any more of it. Pea also is catching up. Egg is freer than stove. Steam sizes are very slow and even cut prices by the small producer is moving only a limited tonnage.

There is still uncertainty as to prices in the Baltimore market. There are some in the retail trade who would like to prevent a raise, if possible, but others feel that the retail trade has already gone too far in absorbing the wholesale advances that have taken place since May 1. Should there be wholesale advances for July it seems almost sure that a minimum raise of 25c. per ton must take place in retail prices.

## Foreign Market And Export News

### British Market Still Gaining Gradually; Output Hard Hit by Holidays

The Welsh coal market is improving, activity showing a gradual but steady gain. The strike of railway shopmen, now settled, has helped somewhat, though power-house operators stayed in. Business with Europe is very poor, particularly with France and Italy. Several big orders have been placed by South America for Monmouthshire large coals at prices averaging 26s. 6d. The Welsh coal field as a whole has been hampered by continual threats of sectional strikes, but tonnage is arriving much more freely. Lower qualities are reported plentiful and prices easier, while the better grades of coal are steadier. Demand is picking up but is still below output. The employment of non-union workers is threatening labor trouble.

The Ruhr settlement has resulted in the withdrawal of many German inquiries from Newcastle. The Paris gas works has contracted for 70,000 tons of ordinary Durham gas coal for shipment from July to December at 20s. f.o.b. Large contracts from the Swedish State Rys. have been allocated.

A cable to *Coal Age* states that the output of the British collieries during the week ended June 14 dropped to 3,236,000 tons owing to the observance of the Whitsuntide holidays, according to the official figures. This compares with 5,120,000 tons produced in the week ended June 7.

#### Trade at Hampton Roads Poor; Market Weakening

Business at Hampton Roads is poor, with the market weakening and movement generally falling off. Indications were June would show the lowest dumping record for the year.

Coastwise trade is less than fair, while bunker business is off and foreign movement showing little change.

The tone of the market is extremely dull, with stocks at tidewater substan-

tially increased and with shippers eager to move their stocks under any conditions to obviate demurrage.

#### New Business Is Scarce In French Market

The French coal market is unchanged. The French collieries are making regular shipments on existing contracts, but are not obtaining any new business, except perhaps for the renewal of expiring contracts. Since the settlement of the Ruhr strike deliveries are nearing their normal scale again. Recently a large number of German inquiries for coal appeared on the free market, but with the political upheaval in France, these inquiries have disappeared.

House coal trade shows the effect of the increase of British anthracites. All the coal syndicates advise their adherents to defer ordering and dealers also suggest these measures.

Indemnity deliveries to France and Luxemburg during May consisted of 243,400 tons of coal; 365,300 tons of coke and 33,900 tons of lignite briquets, a total of 342,600 tons, against 1,301,100 tons in April.

With regard to the renewal or prolongation of the Ruhr agreements, the M.I.C.U.M. heard the usual declarations of the industrialists on their inability to continue the deliveries. After receiving advices from Berlin, the mines and cokeries have accepted a prolongation of two weeks.

It is understood that the next arrangement, which is to be in operation in July, may have a retroactive effect as from June 16 as regards the abolition of the "kohlensteuer" (coal tax) on export permits and derogations and other allowances in species.

During the first ten days of June, the O.R.C.A. was supplied with 103,330 tons of coke, or a daily average of 10,333 tons.

## News Items From Field and Trade

### COLORADO

Oil prospecting on a tract of Routt County land belonging to the Colorado Fuel & Iron Co., is now going on. J. F. Welborn, president of the company, has announced that oil men repeatedly have declared there was oil under some of the company's coal lands, so finally a lease was made on a small tract on Snake River on the line between Routt County and Carbon County, Wyoming, to the Ohio Oil Co., a subsidiary of the Standard Oil Co. Thus, says Mr. Welborn, it will be determined by a reliable oil company whether there is any oil on Colorado Fuel & Iron Co. property without cost to the company.

### INDIANA

E. D. Logsdon of Indianapolis, coal operator and head of the Knox Consolidated Coal Co., the marketing agency for the mines controlled by Mr. Logsdon, has been named by Governor Emmett S. Branch as a member of the state agricultural board. Mr. Logsdon always has taken an active interest in agricultural affairs and is known as a raiser of pure bred cattle.

William J. Snyder, well known coal man of Brazil, who has become a confirmed globe trotter since the coal business slumped, has returned home after having spent the last seven months on tour of the world. He was accompanied by his grandson, Billy Hall, of Indianapolis. During the last tour the two visited New Zealand, Australia and other islands of the South Seas, then voyaging around the southern coast of Asia, through the East Indies to China, Japan and the Philippines and back home by way of Honolulu. While in China, he stopped off for a visit at Shanghai, where his wife, Grace Snyder, was killed by Korean revolutionists March 28, 1922.

The Kentucky Coal Co. was awarded the contract for coal for Delaware County, Ind., at a recent meeting of the Board of County Commissioners at Muncie, Ind. Pocahontas coal is to cost \$4.75 laid down in Muncie and West Virginia will cost \$4.62 f.o.b., Muncie.

### KANSAS

The Italian Coal Co., a co-operative organization of 24 miners, has been given a verdict against the Patton Coal & Mining Co. for \$8,050 by a jury in the Crawford County District Court at Pittsburg. The Italian company leased a mine from the Patton company, which contracted to purchase the entire output. The suit, which was

brought for \$11,150, alleged that the Patton company defaulted in payments. The Patton company claimed that the lessees used so much dynamite that a large percentage of slack was produced while the contract specified they should produce "the largest possible amount of lump."

### KENTUCKY

Judge John Stewart, of Ashland, and Judge Harmon, of Pikeville, Ky., headed a delegation of coal-mine operators of the Big Sandy Valley district, which appeared June 16 before the State Tax Commission at Frankfort in an effort to obtain lower tax assessments on coal properties. They contended that in view of stagnant conditions in the coal markets and falling values, tax assessments are in many cases far beyond the physical value of coal properties. The Edgewater Coal Co., of Pike County, objected to an increase of \$140,000 on an assessment already at \$500,000, and the Big Sandy Coal Co., now assessed at \$1,000,000, got a raise of \$300,000.

### MINNESOTA

Coal receipts by cars in St. Paul during April, just given out, show a loss as compared with April of 1923. Hard coal went from 172 to 117 and soft coal from 2,304 to 1,755.

Fuel oil burners for residential use have not proved a complete success in the Twin Cities. A number of concerns which started out to sell the devices have found that the business was not profitable, and have removed from expensive downtown showrooms to smaller ones located out from that district. Many of the smaller ones have quit completely. And the oil companies are losing interest in the fuel oil, and are getting away from it to the strictly commercial ends. Deliveries have been troublesome, access to the tanks uncertain, and many complaints encountered over deliveries. Indications are that the cost of delivering will be increased as a result of the experience of the last two winters.

### NEW YORK

J. Fred Morlock has severed his connection with the Steamship Fuel Corporation, 33 Rector St., New York City.

The report of the Lehigh Valley Coal Co. for 1923, just made public, shows net income of \$5,237,083 after bond, interest and federal taxes, against an average net of \$3,651,935 for the five years to Dec. 31, 1923. This was equal

to \$4.32 a share on the 212,160 certificates of interest offered to stockholders of the Lehigh Valley Railroad Co., compared with \$3.01 a share for the five-year period. The company's deduction for bond interest did not include provision for any interest on \$15,000,000 of 5 per cent bonds for the reason that the issue was dated Feb. 1 of this year and did not enter into the financial structure of the company during 1923. Interest on this issue for the eleven months of the current year will be a charge against this year's income.

Ralph R. McKee, president of the McKee Coal Co., New Brighton, Staten Island, has been appointed a member of the Board of Education of New York City by Mayor Hylan. Mr. McKee is a graduate of Princeton University.

The Stokes Coal Co. intends to erect a new coal distributing plant on the block fronting the Harlem River between 141st and 142nd Streets, New York City.

### OHIO

The offices of the Ohio Utilities Co. were removed July 1 to 150 East Broad Street, Columbus, according to an announcement by J. C. Martin, vice-president and general manager.

Gaylord No. 2 mine of the H. Walker Coal Mining Co., near Yorkville, resumed operations June 23 after a suspension of several months. The company is said to have obtained a contract for railroad fuel.

The sophomore miners of Case School of Applied Science, Cleveland, are taking their practice term in mine surveying at the Grant Coal Mine, Salineville, under the instruction of Anthony Jenkin, associate professor of mining engineering.

Based on sealed proposals received June 4 by the city Board of Purchase for approximately 700 tons of 2-in. screened Hocking Valley coal to be delivered in amounts specified by the chief of the Fire Department to the various engine houses of the city, the contract was awarded to the Lewis & Noon Coal Co., Columbus, on a bid of \$4.30 a ton.

Cincinnati wholesalers and operators in southeastern Kentucky are keeping a close eye on the deal by which the Louisville & Nashville hopes to gain complete control of the C. C. & O. Ry. Already large terminals are being placed at Whitesburg, Ky., and work is proceeding that will allow the Hazard people an outlet to the seaboard. With

this, they say, an entirely new era for southeastern Kentucky coals can be looked for.

The branch office of the Three States Coal Co. in the Frederick H. Schmid Building, in Cincinnati, will be closed as of July 1 and Frank Beazley, who has been in charge for nearly two years, will return to Bluefield, W. Va., the head office, where the business of the company will be transacted, according to advices that have been given to associates in the trade at the Queen City.

H. M. Harvey, president of the Harvey Coal Co., of Knoxville, has been in Cincinnati for several days past, called by reason of the hearing of the suit of his company for the return of its mining property in the Hazard district from Jewett, Bigelow & Brooks in the United States District Court at Covington, Ky. The mines were purchased on the ten-year payment plan and it is charged that the J. B. B. company defaulted on payments over a year ago.

## PENNSYLVANIA

Fire, June 24, destroyed the tippie and equipment of the Yukon Coal Co., at Yukon, near Greensburg, Pa., entailing a loss of \$30,000. Rebuilding plans will be announced in about two weeks.

The Newborn mine, near Carrolltown, Cambria County, was put into operation last week after a lengthy shutdown. John Kelly, Carrolltown operator, is superintendent of the mine. Most of the miners are residents of Carrolltown and welcome the return to work.

State Mine Inspector C. H. Nesbitt has just completed his statistics on coal-mining operations for 1923 and turned them over to the printer for publication in pamphlet form. Coal production reached the record figure of 20,919,303 net tons, with a coke production of 4,689,641 tons, almost the entire coke tonnage—94.8 per cent—having been turned out by byproduct ovens.

The St. Clair Coal Co. is about to erect a new steel breaker adjacent to

its present breaker at St. Clair. The new plant will be equipped with three cone separators having a capacity to prepare about 1,400 tons of coal per day. The structure and equipment will be designed by H. M. Chance & Co., of Philadelphia, a license contract having been signed covering the use of the Chance sand flotation process at the plant.

E. S. Sheets, who a year ago purchased Ira Barron's coal interests south of Somerset, which includes a vein of cannel coal, has disposed of his holdings to the Superior Coal Co., formed by Attorney Ross E. Scott and James Davis, of Somerset. Mr. Davis is owner of an adjoining mine, and the entire acreage will be mined through the opening on the Davis property. The consideration was \$15,000. Mr. Sheets will move to Windber.

Workers taking matches, pipes or cigarettes to the mines of the Glen Alden Coal Co. at the Loomis colliery, Hanover Township, will be discharged, it was announced in the local press following the recent disaster at the colliery. This order at the Loomis, as well as other Glen Alden operations, is not a new one, company officials stated. It had been in effect long before the fatal explosion occurred several weeks ago.

Twenty-two candidates were successful in the nomination for first-grade mine foremen, 72 for second-grade certificates, 21 for first-grade assistant mine foremen and 41 for firebosses, according to an announcement by Mine Inspector Nicholas Evans, head of the board of examiners for the nine districts in the central Pennsylvania field. The examinations were conducted in Johnstown on May 27, 28 and 29. Additional examinations will be held at State College and in Pittsburgh on July 16, 17 and 18.

"When a Man's a Miner," a moving picture shown at the last meeting of the Pennsylvania Mining Institute held in Johnstown, showed conditions of a modern mine at Tiptonville, Ohio. A number of interesting scenes were shown, including a fall of roof which imprisoned miners for several days. "High and Low Voltage" was discussed

by Patrick Nairn, William Duncan and John Gelatly, of the Ohio Brass Co., of Pittsburgh. Papers on "Mine Cars" and "Mechanical Coal Loaders" were read by representatives of manufacturers. Talks on safety were given by Dean Holbrook and William Duncan, of State College. No more meetings will be held until Oct. 17.

The Bertha-Consumers Co., Pittsburgh, has issued \$2,000,000 first mortgage 7 per cent sinking-fund gold bonds dated June 1, 1924, and due June 1, 1934. The company has a capital of \$4,150,877 in 7 per cent cumulative preferred stock and \$4,908,458 in common stock and owns mineral rights underlying 4,443 acres of developed coal lands and leaseholds of additional mineral rights underlying 422 acres of developed coal lands in Allegheny and Washington counties, Pennsylvania, and Brooke, Monongalia, Marion and Kanawha counties, West Virginia. The total coal recoverable from these properties is estimated at 27,753,900 tons.

Of the 157 fatal accidents in the industries of the state in May, according to the Bureau of Workmen's Compensation of the Department of Labor and Industry, sixty-two occurred in the anthracite and bituminous mines. Forty-three fatalities occurred in the anthracite region and nineteen in the bituminous field. The largest number of mine fatalities in the anthracite district during May was recorded from Luzerne, which had eighteen deaths in the mines and only two in all other industries. In the bituminous counties Allegheny and Fayette led with four mine fatalities, each, Allegheny reporting eighteen other deaths due to industrial accidents and Fayette two deaths not attributed to the mining industry.

Two new all-steel towboats of modern design, built for coal and steel trade, will begin service in Pittsburgh waters during July. One is the steamer Donora of the American Steel & Wire Co., and the other is the steamer Sailor, of the Jones & Laughlin Steel Corporation. The Donora is being completed at the Howard Shipyards Co., Jeffersonville, Ind., on the Ohio River, and will be delivered early this month. The

Some Indian Mines Still Hoist Coal This Way

The photograph, from the Geological Survey of India, shows a winding gin near Charanpur, in the Raniganj coal field. Women in the merciful shade of the thatched roof, wind a 500-lb. load in a bucket up through the shaft. From the bucket it is usually loaded in a coal tub on a four-wheel truck and moved to a storage pile awaiting shipment.

Sailor is nearing completion in the yards of the Marietta Manufacturing Co., Point Pleasant, W. Va., also on the Ohio River. It is now almost ready for delivery. Both towboats contain the latest innovations in design and equipment for heavy duty in handling big tows of steel and coal on the Monongahela, Ohio and Mississippi rivers.

## UTAH

The acquisition of one-half of the stock of the Denver & Rio Grande Western R.R. by the Missouri Pacific carries with it the transfer of one-half of the stock of the Utah Fuel Co. It is not expected, however, that this will involve any changes in the operation of the big coal company.

Coal production in Utah during May was 260,586 tons, compared with 311,955 tons for the same month last year.

## WASHINGTON

Bunkering of steamships is increasing in Puget Sound. On June 14 the Danish steamship Transvaal and the Garland line steamer Carolinian, both cargoes with lumber for long voyages, coaled simultaneously at the Pacific Coast Coal Co.'s bunkers in Seattle—the only bunkers on the coast large enough to coal two such ships at once.

Hereafter the Indian Mine of the Pacific Coast Coal Co. will be known as the New Black Diamond, according to an announcement recently made by officials of the company. It is still in the development stage. The intention of the company, however, is to tap the famous McKay seam, which has been worked for many years at Black Diamond, a few miles further east, and preliminary surveys have indicated that this objective will be attained. The new mine is intended ultimately to supplant the Black Diamond mine, which is now the deepest coal mine on the American continent and nearing the end of profitable productivity. It is expected that New Black Diamond will be brought into full operation within the next few years. Several hundred thousand dollars is being spent by the Pacific Coast Coal Co. in developing the mine.

## WASHINGTON, D. C.

Appropriations by Congress of \$1,900,468 will be available for the Bureau of Mines for the fiscal year beginning July 1. They include investigation of mine explosions, \$359,768; mine inspection, \$35,000; mine rescue and safety, \$262,300; purchase of mine rescue car, \$40,000; mineral fuel investigation, \$138,280; ore studies, \$128,360; oil and oil-shale investigations, \$500,000; administration of leasing law, \$91,360; mining experiment stations, \$200,000; Pittsburgh station, \$57,400; and maintenance of government fuel yards, the expenses to be paid out of the receipts. The Geological Survey is given \$1,706,482. These funds include topographic surveys, \$500,000; geologic surveys, \$333,722;

investigation of mineral resources of Alaska, \$75,000; examination and classification of lands, \$280,000. The General Land Office is given \$700,000 for surveying public lands, including inspection of mineral deposits and coal fields.

## WEST VIRGINIA

A station is to be opened in Huntington on July 1 by the U. S. Bureau of Mines. W. H. Forbes will be in charge of the office, which will be located in the federal building. Mr. Forbes will direct the mine safety service work in southern West Virginia. "Although the bureau has had a mine safety car in the state doing mine safety work since 1910, it has just been decided to open engineer's headquarters here to keep in closer touch with mining men," declares Mr. Forbes. He stated that he would be glad to take care of all requests from mining men for the examination of mines and report as to their condition. Huntington will be headquarters also for the mine car, which is equipped with all safety devices pertaining to mining.

The Hisylvania Coal Co., chartered under the laws of the State of Ohio, of which E. W. Blower of 8 East Broad Street, Columbus, Ohio, is secretary, has been authorized to transact business in West Virginia.

The following West Virginia coal concerns have increased their capital stock in the amounts given: Coe Pocahontas Coal Co., from \$200,000 to \$300,000; The Kalbaugh Coal Co., Inc., from \$25,000 to \$50,000; Buffalo Eagle Colliery Co., from \$500,000 to \$800,000; Glade Creek Coal & Lumber Co., from \$2,000,000 to \$2,150,000. The Fat Creek Coal Corporation has reduced its capital stock from \$100,000 to \$35,000; the Kanawha Valley Coal Co. has changed its capitalization of \$2,000,000 to 100,000 shares of common stock at \$10 and 10,000 shares of preferred stock at \$100,000.

The Pocahontas Fuel Co. has decided to close down the Itmann mines, in the Wyoming County field, for an indefinite period. This makes fourteen plants in the Winding Gulf district now in idleness because of lack of sufficient business to justify operation. Loading at other mines in the same district, however, is being increased and operators are inclined to believe that by mid-July it will be possible to operate plants on an average of from four to five days a week.

## CANADA

The Dominion Coal Co. is opening a new mine, to be known as No. 1B, on the sea coast near the town of Dominion, N. S. The new shaft is equipped to produce coal for 100 years. A tunnel 10 ft. high has been cut in solid rock above the seam, and electric haulage locomotives will be used.

It is reported that the coal miners of Fernie, B. C., are considering a settlement of the strike now on through-

out District No. 18, United Mine Workers, which includes eastern British Columbia and the Province of Alberta, insofar as it affects the collieries of the Crow's Nest Pass Coal Co. The signing of a local agreement with the company was discussed at a special meeting and officials of the union have been called to the district to avert such action.

Coal production in British Columbia for the month of May totaled 114,752 tons. This compares with the average of 200,000 tons, showing the result of short working time. In the Crow's Nest Pass there is no output because of the strike. Although there is peace between the employers and employees in the Nicola-Princeton and Vancouver Island fields the demand is so weak that the collieries are unable to maintain operations at anything like capacity.

## New Companies

**The British Canadian Coal Co., Ltd.**, has been incorporated with a capitalization of \$500,000 and head office in Montreal by Harold Fisher, Livius P. Sherwood and Stanley M. Clark.

**The Valentine Coal Co.** has been incorporated with a capital stock of \$60,000 in Worland, Mo., by H. L. Rogers, A. A. Grimmel and others. Mr. Rogers is president of the company.

**The Missouri-Oklahoma Fuel Co.** has been incorporated in Muskogee, Okla., with a capital stock of \$700,000, by Wm. McKinnon, of Kanima, Okla.; E. D. Holley, Stigler, Okla., and others.

**The Tennessee Coal Mining & Timber Co.** has been incorporated in Chattanooga, Tenn., with a capital of \$500,000, and is reported to have purchased over 20,000 acres of coal and timber land near Coal-mont, Tenn.

**The Oliver Fuel Co.**, a Philadelphia concern, has been chartered under the laws of the State of West Virginia, with a capital stock of \$50,000. Those principally interested in the company are J. A. Bal-lenger, of Mullite, N. J.; C. P. Hagenlocher, F. D. Jones, W. Kaufman and William LaBelle, all of Philadelphia.

## Industrial Notes

**The Denver Rock Drill Manufacturing Co.**, of Denver, Colo., recently opened a Chicago branch office at 817-825 West Washington Blvd., with A. J. Philpott as manager.

**Rome Wire Co.** announces the opening of a sales office with a complete warehouse stock of its products at Ninth Street Terminal Warehouse, 1200 West Ninth Street, Cleveland, Ohio. C. R. Evans, district manager, will be in charge.

To better serve their customers in the Southwest, the **Chicago Pneumatic Tool Co.** has opened a branch office at 210 So. Jefferson Street, Dallas, Texas, with J. O. Bailey in charge, reporting to the New Orleans branch.

**Herman Lemp**, engineer in charge of the internal combustion engine engineering department of the General Electric Co., at Erie, has resigned his connection with that concern to join the Erie Steam Shovel Co. This follows an association with the General Electric Co. for 42 years.

**The Nanticoke Valley Coal Co.**, of Wilkes-Barre, Pa., has just executed a license agreement with H. O. Staples for the use of the Chance sand flotation method at a washery to be located on the property of the Susquehanna Collieries Co. near Nanticoke, Pa., at what is known as the Nanticoke No. 7 bank. The plant will be equipped with a 15-ft. cone separator.

## Traffic News

### South Dakota Would Retain Low Rates on Lignite

The Board of Railroad Commissioners of South Dakota has made a strong plea to the Interstate Commerce Commission in the interest of the continuance of lower rates on lignite than that charged for high-grade bituminous coal. If proposed increases are allowed to go into effect, the use of South Dakota lignite will be restricted to the localities immediately surrounding the mines, it is asserted. The board contends that it is of great economic importance to the Northwest to make use of this low-grade fuel. It is stated that the present lignite rates yield a reasonable revenue and that lignite is entitled to a classification different and lower than coal.

### To Hold Hearing on Proposal to Advance Rates in Ohio

The Coal, Coke and Iron Ore Committee, Central Freight Association Territory, will hold a hearing in Room 606, Chamber of Commerce Building, Pittsburgh, Pa., Thursday, July 17, 1924, at 10 a.m., daylight saving time, on a proposal to increase the rate on bituminous coal, carloads, from mines on the Baltimore & Ohio, New York Central (Ohio Central Lines), Pennsylvania and Wheeling & Lake Erie roads, in the Shawnee, Hocking and Crooksville (Ohio) districts, to local stations on the Baltimore & Ohio R.R., Lexington, Ohio, to Fredericktown, Ohio, inclusive. The advance proposed, from \$1.39 per net ton to \$1.51 per net ton, is to restore these rates to the Mansfield (Ohio) basis, which was the basis in effect prior to Aug. 15, 1919, and which basis or higher is now in effect from other Ohio districts, including short-haul rates.

### Delivery of Pennsylvania's New Cars to Begin Soon

Delivery on the 12,000 freight cars ordered soon after the first of the year by the Pennsylvania R.R. will start this month. The Pennsylvania is preparing to accept between 125 and 150 cars a week during the first few weeks of delivery, with a gradual increase in the number until practically all of the cars will be on line for the movement of the autumn traffic.

### Mistrial in Demurrage Suit

Trial of the test case of the Smokeless Fuel Co. against the Chesapeake & Ohio Ry. to establish a basis for deciding the old war-time demurrage suits, in which practically all coal agencies at Norfolk port are endeavoring to collect approximately \$250,000 from the railway for alleged overcharge for demurrage, was halted in Newport News last week when it was found that a member of the jury was an employee of the railroad. A mistrial was ordered after the case had proceeded for three days, and it has been set for retrial in July.

### Virginian Moves Big Coal Train

The Virginian Ry. on June 9 hauled out of Princeton, bound for Roanoke, a 10,200-ton coal train, using a 700 U. S. Mallet type engine, which is said to be a record with this type of engine. The train consisted of 65 120-ton coal cars. In May, 1921, the Virginian operated a demonstration train out of Princeton consisting of 100 loaded 120-ton cars, but the train was drawn by the big 800 type engine.

## Obituary

Edgar M. Reynolds, vice-president and comptroller of the Lehigh Coal & Navigation Co., of which he had been an officer for more than 20 years, died at his home in Germantown, Philadelphia, June 16, after an illness of four weeks. He was born in Newark, N. J., in 1861, and had 19 years' experience in the railroad field before joining the L. C. & N. At the time of his death he also was an officer and director of several companies affiliated with the L. C. & N.

## Trade Literature

**Webster from the Air.** Warren, Webster & Co., Camden, N. J. Pp. 30; 6x9 in.; illustrated. Contains aerial photographs of cities where the Webster steam-heating system has been installed.

**The Century Wood Preserving Co.,** Pittsburgh, Pa., has issued a four-page folder describing the advantages, effectiveness, construction, capacity and reliability of the **Shipley Treating Unit** for timber preservation.

**Wire Rope.** Macwhythe Co., Kenosha, Wis. Pp. 80, 5½ x 7½ in.; illustrated. Describes uses and kinds of wire rope and fittings, being designed to answer all questions pertaining to wire rope in as few words as possible.

**Tempo Shower Washing Equipment for Mine, Mill and Factory.** James H. Channon Mfg. Co., 223 West Erie St., Chicago, Ill. This 6-page folder describes and illustrates showers, wash-sink faucet and water tempering system.

**High and Dry.** James H. Channon Mfg. Co., 223 West Erie St., Chicago, Ill. Pp. 17; 6x9 in.; illustrated. Describes the Union sanitary clothes hanger suspended by chain and pulley from the top of the room, with a basket arranged to hang above the clothes for lunch and valuables. Price list is appended.

**Storage Battery Locomotives.** Mancha Storage Battery Locomotive Co., St. Louis, Mo. Pp. 10; 9x10½ in.; illustrated. Among the locomotives described is the **Little Tramper** which will run onto a small mine cage and go to any level like a mine car.

## Coming Meetings

**World Power Conference,** Wembley, London, England, June 30-July 12. O. C. Merrill, Federal Power Commission, Washington, D. C.

**First International Management Congress,** Prague, Czechoslovakia, July 21-24.

**Rocky Mountain Coal Mining Institute.** Summer meeting, Aug. 7-9, Rock Springs, Wyo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

**New York State Coal Merchants Association, Inc.,** 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

## New Equipment

### New Non-Return Valve

The Lunkenheimer Co., of Cincinnati, Ohio, has recently placed on the market the safety non-return valve, intended to be placed on the outlets or nozzles of steam boilers, shown in the accompanying illustration. This device is intended to supplant the ordinary check valve often used on boilers to prevent a flow of steam from the header, or from another boiler back into a unit not in use. As may be seen from the illustration, which shows a section through the device, it consists of what practically amounts to a globe valve with a spring-counterbalanced disk. As may be noted, the spring as well as its adjusting mechanism is external to the valve proper.

The stem of this valve is not connected to the disk, but the disk slides upon it when the stem is raised. Counterbalancing the disk by means of the external spring obviates all chattering of the valve against its seat. When the boiler upon which one of these valves is installed generates sufficient steam pressure to lift the disk from its seat, it is automatically cut into the line. However, should a tube burst or a header in the boiler be ruptured, causing a backflow of steam from the header to the boiler, the valve immediately closes and prevents steam from other boilers reaching the one which is injured.

This valve forms a highly effective safety device in case a boiler is being cleaned. Even if the stem is raised through accident or otherwise, the valve closes the instant pressure from

Half Section of Valve

The counterbalanced seat slides on the valve stem. The valve may be closed by operation of the handwheel but it can be opened only by pressure from below the disk.

the outside is applied and will not permit a back flow of steam into the boiler being cleaned or inspected. In the past, many distressing accidents have resulted from such causes as have just been outlined.

### Gyrating Coal Shaker

Those familiar with present practice followed in anthracite preparation well know the great overall length of shaking screens. Such shakers occupy much space in the expensive structure of the breaker in which they are employed. Could this length be materially decreased it would result in economies out of direct proportion to the actual decrease in overall dimensions.

In order to accomplish this result H. W. Falker, of Ashland, Pa., has developed what has been named the Master screen shown in Fig. 1. This is a development of, or an improvement on the Economy gyrating screen developed by Mr. Falker some years ago. In the original screen the eccentrics driving the screen decks revolved in opposite directions affording elliptical paths of different amplitude to each point on a screen deck, as may be seen in Fig. 2. In order to obviate this difficulty and the unequal wear of the screen which it entailed, in the new device the eccentrics revolve in the same direction. This gives every point on the screen a circular motion equal in diameter to twice the throw of the eccentrics.

Advantages claimed for this machine include the following: All portions of the screen plate are used to maximum advantage and there is small tendency for the holes to wear elliptical. As all points on this screen describe circular

instead of rectangular paths as in the case with the ordinary screen, the effectiveness of the two should be to each other as the circumference of a circle is to its diameter, or as  $\pi : 1$ . Thus the same screening effect should be secured with less than one third the screen area. The floor space occupied by a screen of this kind as compared to that necessary for the ordinary shaker will be even less proportionately, as no long eccentric rods are necessary.

### Totalizing Polyphase Wattmeter

A recent General Electric Co. development is a totalizing recording wattmeter. This instrument is direct acting and operates on the induction principle. The moving element consists of a shaft approximately 36 in. in length on which are mounted four metallic disks. Grouped around these disks are split-phase torque producing elements, sixteen in number, thus making it possible to totalize any number of polyphase circuits from two to eight. A strip chart, 6 in. in width, is employed, and the record is made by a siphon type pen connected to the moving element through a simple link. The high torque of this instrument makes it available for operating remote indicators.

A complete line of remote indicators for use in conjunction with these instruments is now available. These indicators are of various styles and sizes but are all operated by Selsyn motors, actuated by a Selsyn transmitter geared to the shaft of the wattmeter instrument. This Selsyn system consists of a transmitter and

Wattmeter for Totalizing Power

This instrument is composed of many metering elements so connected that it is possible to totalize the consumption of power in from two to eight polyphase circuits.

motor so connected electrically that rotation of the transmitter causes a similar rotation of the motor. Manually operated transmitters and indicators are supplied as well as combinations of both manual and automatic indicators.

### Steel Transmission Pole

The Truscon Steel Co., of Youngstown, Ohio, has recently placed on the market the new steel transmission pole shown in the accompanying illustration. Poles of this kind may be manufactured in all sizes up to 50 ft. in length. One salient feature of this new steel pole is its simplicity of construction, being pressed from 5 in. to 12 in. steel channels or I-beams. The design is such that no special equipment is needed by the lineman for ascending or descending, thus eliminating all necessity for climbing spurs or steel steps.

This pole is adaptable not only to transmission and distribution lines, but to telephone, trolley and street lighting systems. It is made by pressing a portion of the web of a channel or I-beam out to a predetermined angle and then riveting this section to another of a second channel or I-beam. Before this pole was placed on the market in quantity, it was subjected to practical tests under varying conditions for a period of two years. It is claimed by the manufacturer that when this pole is anchored in concrete and painted once every five years, it will last indefinitely. It is also maintained that because of the ease of its manufacture, it will ordinarily cost about the same as a wood pole. In some sections of the country its cost may be less.

Fig. 1—Side and End Views of Gyrating Screen

Two vertical eccentric shafts revolve in the same direction, thus imparting a rotary motion to the screen decks. A screen with any even number of decks may be balanced so that vibration is neutralized.

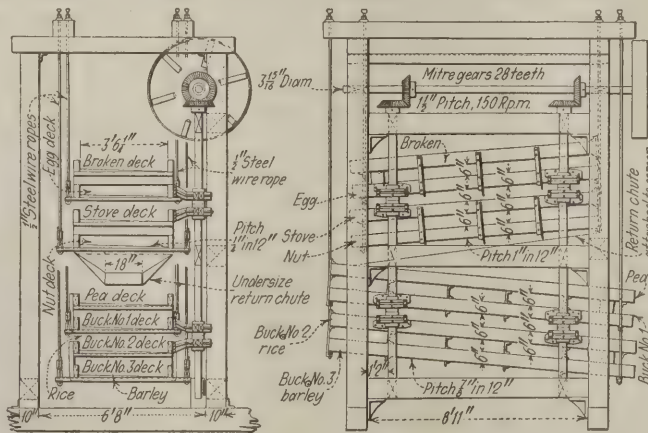

Fig. 2—Unequal Travel Imparted by Opposite Eccentrics

Revolving the two vertical shafts in opposite directions impart an unequal travel to all parts of the screen, each point upon it moving in a more or less elongated ellipse. This results in unequal wear of the screen plate.

## Every Man Has His Own Gas Plant

EVERY house furnace gasifies its own fuel and burns the gas for heating. Isolated units of such small dimensions would seem utterly uneconomical. They may pass eventually into the discard, but just at present the household furnace seems firmly established with all its inefficient combustion and its high costs of attendance. Surely the gas men must find a better way before long, but until they reduce the price of gas the present antiquated system will continue. The gas men certainly should explain why they have been making so little of their large opportunities.

## Everybody Happy

PARTIES having opposing interests rarely succeed in writing consistent platforms. The recent Democratic program has this character of inconsistency. To please certain Western delegates the following plank was written: "Mining is one of the basic industries of this country. We produce more coal, iron, copper and silver than any other country. The value of our mineral production is second only to agriculture. Mining has suffered like agriculture and from the same causes. It is the duty of our government to foster this industry and to remove the restrictions that destroy its prosperity." This plank will be a good one to appease the demands of the mining region, especially in the West.

The coal men do not ask to be fostered, not at least in the year of grace 1924. Not since the war has the coal man had the notion that he wanted governmental coddling. Before the war the coal industry in Illinois believed it might be possible to obtain a modification of the Sherman Act to allow the forming of a combination that would permit the fixing of a fair price. The Illinois operators believed that they might, and should be, allowed to follow the example of Germany under government supervision. Soon after, they found the market favored highly profitable operation and changed their minds. When their balance sheet showed black figures they became opposed to any government control and so no longer advocated any change in the law.

The plank just recited seems to them suprisingly equitable and more than they could have hoped to attain, but its strength is sapped by what follows: "We pledge the Democratic party to regulate by governmental agencies the anthracite coal industry and all other corporations (sic) controlling the necessities of life, where public welfare has been subordinated to private interests." That will please the consumer states, especially New England. So the platform in places suits both consumers and producers, all according to the particular plank quoted.

It is ill written because opponents in consumer states can quote the anti-consumer plank and in producing states can quote the anti-producer plank. Consequently the program is acceptable to everybody—to Republicans

because it can be quoted against the Democrats, and to Democrats because the plank can be quoted to Democratic audiences as the audience addressed would prefer. The mining planks, therefore, are masterpieces; everyone will find in them just what he wants to prove his case.

## Knowing Versus Guessing

NOTHING is safer than knowing, yet how few are the companies who really know just what they are doing. Nevertheless, more is known today than even a few years back. Most of them know the labor cost of mining, deadwork, ventilation, trackwork, drainage and so forth, but almost none know the actual power costs of these various items and few the supply costs. They cannot compare the power and supply costs between mine and mine, nor tell how they vary from month to month. Having no means of comparison they do not know which are high and which low and cannot tell what they should do to keep the costs down.

If, however, it is well to know labor costs; if knowing the costs has reduced them, surely it would be advantageous to learn the power and supply costs in order that similar efforts may be expended in their reduction. It would be well to meter the various power uses, to know how the power, supply and repair costs of locomotives, machines and fans vary so that economy may be sought in each and rules be formulated that will reduce them all to an irreducible minimum. When we can set a mark at which to aim, we can come nearer the goal. Of course, costs will vary with grades and distances in the case of locomotives, with the kind of coal cut in the case of machines and with the resistance and air delivered in the case of fans, but by a comparison of month with month and operative with operative much will be learned and costs will be reduced. Between knowing and guessing, who will not choose the former?

## Have a Heart

TOO OFTEN the wiring diagrams furnished with electrical equipment, especially for automatic apparatus, are too complicated for even a professional puzzle expert to unravel. The Behistun rock has no more perplexing symbols.

To the designing engineer who is forever dealing with complicated connection diagrams a statement like this probably sounds foolish. Perhaps he would be inclined to be even a bit critical and say that the man who couldn't follow his diagram was not much of an engineer.

But almost every electrical manufacturer uses signs and symbols peculiar to his own drafting department, and the mine electrical engineer, who of necessity must purchase equipment made by many different companies, must learn the particular style of each.

It is not unusual to find the electrical equipment used

in any modern substation or power plant made by six or seven different manufacturers. Often this means that six or seven wiring diagrams must be understood and then changed into one which shows the whole wiring layout of the plant.

Would it not be advantageous for the manufacturer to simplify these diagrams, standardize them a little more, so that the mine engineer would not be scared away from buying new forms of equipment which would suit his requirements much better than the old types with which he is more familiar? Manufacturers must not forget that the equipment must be maintained by the men at the mines who, rather than admit they do not understand certain wiring diagrams, very heartily condemn apparatus which is accompanied by a complicated connection blueprint.

Manufacturers should never overlook that progress in industry always has been delayed by the fear of the purchaser or his agent that he will not be able to handle the equipment satisfactorily. Consequently it pays to depict the connections so that they will be understood, and to design the machine so that a minimum of information and brain power will serve to operate it.

### As It Is Done Abroad

**A** REPORT on the Causes of and Circumstances Attending the Inrush of Water Which Occurred at the Redding Colliery, Falkirk, Stirlingshire, on the Twenty-fifth of September, 1923," by Sir Thomas H. Mottram, Chief Inspector of Mines, and presented to Parliament by command of His Majesty, appears on the editorial desk. This little book is headed by the royal arms with the lion and the unicorn as supporters. It has thirty pages of text and five large folding plates.

Only forty men were killed at the Redding Colliery by that inrush of water. We have been wondering how many volumes of text would be written and possibly should be written here about our mine disasters, often larger and always more numerous than those in Great Britain, if we gave printing space to the subject equal to that which is devoted to it there.

But we let the press carry the story. We shudder, pass on and forget. Perhaps if we took the matter more seriously it would be possible to reduce the number of accidents. Our state reports in earlier years used to enter into much detail on mine accidents and explosions, gave maps that illustrated the whole story and showed interesting devices for promoting safety. Today accidents are boiled down to statistics—the number of victims, the date of the occurrence and little more. We have become calloused to the misfortunes of our mine workers. The story hardly ranks any longer as a headline.

As for the Redding disaster, on which this little preachment was based, it was caused by an uncharted area in an old mine that had filled with water and was potential for mischief. The water escaped through a dyke from a seam higher up and drowned the men. It appears likely that a new law further defining the proper procedure in places approaching water will be passed to prevent such accidents in future or that the Water Dangers Committee will prescribe the removal of all such dangerous accumulations of water. The report recommends the use of more telephones, that the miners be better informed as to emergency exits and that someone be placed in charge of the deputies on the night

shift. One is impressed with the idea that the report gives evidence of an activity that will endure. If in the United States we had an accident Sept. 25 of one year it would be forgotten by April 1 of the year following, the date when the account of this disaster with comments was forwarded by the Mines Department to E. Shinwell, the Secretary of Mines. Is this patience in following up disasters the cause for the low fatality rate per thousand men employed now attained by Great Britain? Is the interest of Parliaments in a disaster of the kind eight or more months after its occurrence a reason why mine accidents are less frequent and less destructive in at least some lands beyond the seas?

### Acquaintance Takes Edge off Disagreements

**W**E HEAR so much about the failure of civilization in the World War and in other ways. We forget that in times past war was the normal state of peoples and that it is still quite a usual condition in uncivilized communities. Where people do not meet, except perhaps in battle, they can imagine all kinds of things about each other. Travel and acquaintance make wars less frequent. It is true that civilization has made them more devastating, but it has also made the public less ready to indulge in them.

To know your neighbor is to arrive at a certain degree of appreciation of him. Many a man has been able to revile another till he met him. Many men with intense animosities are disposed to keep away from their adversaries lest closer acquaintance cause a reconciliation. Few people can harbor a resentment against those they know well.

As the outward appearance of a man is usually a symbol of his character, the press has done yeoman service for international, national and industrial unity and good will by publishing portraits of prominent men. Plant publications always make much use of portraiture. A sort of kindred feeling arises among men who know at least the outward seeming of those with whom they are associated in business and other relations.

We wonder that the press finds so many camera-shy men. If a man has a face that radiates good will, that betokens a spirit of kindness and fellowship, that shows the bearer of it to be animated by good purposes he should not be unwilling to have it reproduced. He may be sure it will do much to promote harmony and good will. Hardly any face is so devoid of manliness and humanity that the publication of an illustration of it will not serve a good purpose and widen the circle of the man's wellwishers.

The candidates for office are wiser in their generation than the average business men. They have their countenances portrayed on banners, posters and cards as an outward sign of the goodly qualities they possess. He is indeed unwise who keeps from the public those features which have endeared him to his associates and will make his employees and the public recognize him as entitled to their goodwill.

A portrait will usually do more good than reams of panegyric. It will have the advantage of absolute truthfulness. A man cannot harbor mean and unkindly thoughts and purposes without their being reflected in his face. Any man, therefore, who knows his purposes square with the public interest will not be unwilling to let the public see his face or learn, as it has been expressed, "what manner of man he is."

*Machine at work in the No. 2 Gas bed*

## Machines Load More Than 100 Tons per Shift In Mines on Paint Creek, West Virginia

A Large Output per Machine Has Been Obtained, But Mining and Shooting Methods Have Not Yet Been So Adjusted to the Difficult Conditions at These Mines as to Get Full Benefit From Equipment

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*  
Pittsburgh, Pa.

AT KINGSTON, W. VA., on Paint Creek, about 30 miles east of Charleston, the Kingston Pocahontas Coal Co. has four loading machines in operation in its mines. All of these machines are doing good work and turning out large daily tonnages in spite of adverse conditions, natural and otherwise. At Burnwell, 9 miles farther up the creek, the Imperial Colliery Co. has one machine at work in its Imperial No. 4 mine. This loader also is doing well both in tonnage produced and in costs registered. The former company began its experiments about 18 months and the latter firm about a year ago.

Both of these companies have gained sufficient experience with mechanical loaders to enable them to accurately sense the requisites for satisfactory machine operation under the conditions existing in their respective mines. Neither has any complaint to make concerning the capacity or productiveness of the machines themselves, both attributing the only moderate degree of success thus far attained from their use to the natural conditions encountered and the methods of mining followed.

NOTE—Coal in headpiece shows the results of heavy shooting. In spite of this, however, much of the coal hangs in the corners and has to be broken down by hand. The flat lumps on the machine are portions of a band of tough woody coal that occurs near the bottom of the bed.

So far as output per machine is concerned both companies have been highly successful, as well over 100 tons are regularly loaded per 8-hr. shift. This compares favorably with the results generally obtained elsewhere. Nevertheless, there still remains room for vast improvement. This will be gained by adjustments in the room layout, track arrangements, the methods employed in shooting the coal, a proper distribution of labor and assignment of duties in well-planned schedules and cycles of operation. All this will take time and study. The resident officials at the mines of each company realize the disadvantages under which their machines operate and the inefficiencies in their present practices, and make no attempt to conceal either. Each day they get new ideas and see ways by which their methods may be improved. Changes are being made slowly but surely.

In the mines of the Kingston Pocahontas Coal Co. the four machines have proved their ability to load coal easily at a rate of one ton per minute, and to move from place to place as rapidly as a cutting machine can be shifted under similar conditions. Nevertheless, they have not been economical when working in rooms, though they save money in entry driving. One mine car after another has been loaded at the rate stated. Throughout December, 1923, each of two machines

working the Eagle bed in the Westerly mine of this company averaged 120 tons in eight hours.

Notwithstanding this excellent performance, however, the labor cost per ton of machine-loaded coal is no less, or at least, not appreciably less, than that of hand-loaded coal. This discrepancy does not lie with the degree of efficiency of the labor employed. The saving made in actual loading is more than counterbalanced by the cost of deadwork.

#### LARGE TONNAGE MAY NOT SIGNIFY LOW COST

It is one thing for a loading machine to be successful in performing its duties, but quite another for it to be economical. A measure of any machine's economy is not the number of tons of coal it will load in a given time, but rather the number of men required to win and prepare the coal, as well as the average return realized per ton on all sizes made. Even under unfavorable conditions the rate of machine loading may be speeded by employing during the off shift enough additional men to prepare the places properly for the operation of the loading machine. A loading machine, however, which may be economical under certain conditions may be quite uneconomical under those less favorable. This circumstance, however, casts no reflection whatever upon the machine itself.

In the mines of this company the Eagle bed exhibits several characteristics of the Pittsburgh seam in the Connellsville region. Both beds yield coking coals; their analyses are similar, and little difference is noticeable in their physical texture. The bottom is of fireclay which when wet makes the shifting of a loading machine difficult. Ten inches of drawslate overlies the coal which has an average thickness of about 7 ft. Above this slate is a soft shale bed which slacks, on exposure to the air and comes down to heights of as much as 7 ft. above the top of the coal.

In places the roof above the Eagle seam, like the drawslate above the Pittsburgh bed, pinches out, leaving in its place a hard sandstone top. Unlike the Pittsburgh bed, however, in limited areas of the mines, a middle parting separates the Eagle seam into two benches. The cover above the mines of this company is much thicker than that generally found overlying the Pittsburgh seam, for the properties are situated in a mountainous section of Kanawha County. The roof breaks without difficulty when the work in rooms and pillars is done in proper sequence.

The many characteristics common to both the Eagle and Pittsburgh beds make practically the same mine layout desirable in both measures. The Kingston Pocahontas Coal Co. drives its rooms 20 ft. wide and 300 ft.

long on 60-ft. centers. Necks are driven 12 ft. wide and about 25 ft. long. Pillars are recovered in practically the same manner in the Eagle as in the Pittsburgh bed. Loading machines are not utilized for pillar drawing. So far as this process is concerned, however, loading machines are seldom so employed anywhere. Occasionally, in the mines of this company, one or two slabbing cuts are loaded out mechanically before the pillar is brought back by the usual methods of hand loading.

The drawslate above the Eagle bed in the mines of the Kingston Pocahontas Coal Co. has prevented material savings being made in the mechanical loading of coal. Where this slate is sound and the coal is loaded by hand, it can be kept in place by careful timbering. With machine loading there is little choice between keeping it up with timber and taking it down. When unsupported for 12 ft. from the face what is apparently sound roof will spring, so that it must be taken down. When the slate is supported by timber a loading machine can be maneuvered only with difficulty, for the timbers have to be shifted, which is a hazardous operation. To take this slate down before the loading machine enters the place is prohibitively expensive, for it costs approximately as much to load it by company men as is saved by the loading of coal by machine. The additional picking, which mechanically loaded coal requires, should be added as another item of expense.

#### NIGHT LOADING ASSURES PLENTY OF CARS

In these mines loading machines are used on the night shift so that a sufficient number of mine cars can be furnished to keep the machines busy. Obviously this is the best procedure to follow, because, if practiced simultaneously, the operations of machine-loading and hand-loading would conflict. The two cannot well be prosecuted at the same time.

To load 120 tons by machine in eight hours 14 men working in two shifts are required. Six men are employed on the night shift—a machine runner, two helpers, a trimmer, a motorman and a trip rider. Sometimes, when the locomotive is coupled to the mine car being loaded, the trip rider trims the coal and picks as much slate from it as he can. In the absence of the trimmer during the shifting of a loaded trip to the parting, one of the machine helpers takes his place. With this arrangement only five men are employed on the night shift.

There should be little need for a trimmer. Mine cars loaded by machine should not be heavily topped, nor can the trimmer pick out much slate so rapidly does the machine load the cars. The two helpers facil-

FIG. 1

#### Drilling Shotholes

Electric coal drills used at the face save much labor. Six shots are ordinarily necessary to bring down a face in the No. 2 Gas bed for loading mechanically as against three with hand loading. Positions of holes to be drilled are indicated by the chalk marks on the face.

FIG. 2

### Squaring Break-through Face

In the Imperial No. 4 mine the mining machines cut a kerf below the 4-in. band of tough woody coal. The strong roof requires little timbering. This allows ready movement of both undercutters and loading machines. A tender roof sometimes requires so much timber that the machines can be maneuvered only with difficulty.

itate speedy loading by shoveling coal at the face into the path of the machine when they are not engaged in picking down hanging coal. With more study will come a solution of the problem of shooting the coal to advantage. This should eliminate at least one of the helpers.

On the day shift eight men are employed in preparing the faces for the loading machine. The duties of four of these men include the shooting of coal, laying of track and timbering. About half the time of a cutting crew, or the full time of one man, is required in undercutting the requisite number of places to yield 120 tons of coal. Three are engaged in handling slate. This represents a heavy labor charge, which is not incurred where the roof directly above the coal is sound.

At least 80 per cent of the coal produced by this company from the Eagle bed is sent to byproduct-coke plants. In consequence, when shooting, no attempt is made to obtain a large percentage of lump. Places are center-cut by breast machines mounted on trucks. The bottom bench, of course, is shot first. From 6 to 10 shots are used depending upon the width of the place. Heavy shots are fired in order to bring down as much of the coal as possible, for no tight corners or hanging coal should be left on any part of the face.

In this 7-ft. bed it might be possible to use loading machines economically merely by top-cutting and leaving about 1 ft. of coal to hold the roof. The saving that might result from not having to handle draw-slate, the greater efficiency secured from the machines themselves and the elimination of part of the labor charge for picking no doubt would more than offset the loss of coal left in the roof.

A 6-ton reel-type locomotive is kept in constant attendance on each loading machine. Until the first crosscut in a room is driven, loaded mine cars are stored on the track of the butt entry. When starting to load a cut a locomotive pushes four empties into the room, remaining with them. After the rear car is loaded, the trip is pulled out of the room and the load uncoupled on the straight track. The locomotive pushes three empties into the room, and so on, going through the same cycle for all but the last mine car. This last car is spotted under the conveyor of the machine, and the locomotive is uncoupled. It then leaves the room, and is coupled to the three loads on the entry, which it takes to the parting, returning with three empties.

In rooms that are further advanced a switch and track are maintained in the crosscut nearest the face

for the storage of cars. With this arrangement little time is lost in shifting. A  $3\frac{1}{2}$ -ton mine car may be filled with 3 tons of coal in 3 min. when the faces are properly prepared. The average time of replacing a load with an empty at the machine is  $1\frac{1}{2}$  min.

Conditions detrimental to the economical use of loading machines in rooms are less serious in entries. These passages are driven 12 ft. wide. Narrow work, as might be expected, develops less roof trouble. For rapid development machines should load two cuts per shift on each entry face.

This company by no means has given up the idea of using loading machines in rooms, for in one section off 14- and 15-right entries the coal thus far mined has a sandrock top which, if it persists, is ideal for loading-machine operation.

### HAVE HAD MACHINES EIGHTEEN MONTHS

During its 18 months of experimentation with mechanical loading the Kingston Pocahontas Coal Co. has attempted to measure the ability of machines to supplant hand labor. Regardless of the outcome of the experience so far gained, it has profited from it. It knows what changes should be made and what conditions must be overcome to make mechanical loading profitable in its mines. Best of all it has proved the worth of loading machines for driving entries.

At the Imperial No. 4 mine of the Imperial Colliery Co., Burnwell, W. Va., one loading machine is used in the No. 2 Gas bed. During one year's service this loader has conclusively established a claim for putting coal on a mine car at a cost less than would be incurred in loading by hand. All work connected with the mining of coal by this machine is performed by company men.

The physical properties of the No. 2 Gas bed of the Imperial No. 4 mine are more favorable to machine mining than those of the Eagle seam in the mines of the Kingston Pocahontas Coal Co. In the latter the coal is 7 ft. thick, and in restricted areas is divided by a 6-in. parting. It has a roof of drawslate subject to weathering on exposure to the air, and a fireclay bottom. The advantages in the Imperial No. 4 mine are such that a saving of 24c. per ton is obtained by the use of the loading machine.

In this operation the roof is of massive blue shale that possesses interrupted cleavage and which stands with a minimum of timbering. Directly above this slate is a 30- to 40-ft. bed of hard sandstone. The cover,

Fig. 3—Double Track to Facilitate Loading

The two spur tracks are joined to the room track by a sliding joint. Four or more cars in a trip may be so shifted by a locomotive as to keep an empty car available for the loading machine most of the time. The track was laid temporarily in order to get the picture from which this illustration was made. In actual practice steel ties are used exclusively.

attaining in places a thickness of as much as 800 ft., is divided at widely separated points by vertical cracks, known locally as "surface seams." The depth to which these cracks penetrate the cover is not known, but it is supposed that they extend into the sandstone because of the apparent ease with which the cover moves along these surfaces of weakness, also because of the flow of water through these channels. Within the coal they may be traced by rusty films or stains.

Though the bottom is of shale, and to all appearances hard, it heaves in some parts of the mine when pillars and barriers take on the weight resulting from a cover that is difficult to break. In one instance 400 ft. of entry heaved even though protected by solid barriers. In pillar sections the bottom often moves over night. This difficulty becomes most serious in drawing the stumps of room pillars, also in removing entry pillars and barriers. In some cases it becomes necessary to lift track, take up the bottom, and then replace it. The characteristics of roof and bottom are not as serious as might be imagined, but those of the roof to a certain extent influence the direction of rooms and the establishment of breaklines.

#### LONGWALL OPERATION TO BE CAREFULLY TESTED

The coal in this mine is mined at present by the room-and-pillar system; the company proposes, however, to test the applicability of longwall faces to the physical properties of the roof and bottom as here set forth. If this experiment is made, the company expects to operate a straight face, and to hold the roof by means of stout cribbing and timbering at such a distance from the face that track may be laid along it. It is hoped that by working the face parallel to the surface seams these fissures may be made to assist in the caving of the cover, and the control of the roof.

Experiments in longwall mining in this mine are liable to prove discouraging, for the roof strata are composed of much hard sandstone and the bottom is soft. It is probable that on a longwall face the cover will subside rather than cave. Furthermore, the subsidence of the cover, which is heavy in this mountainous district, would squeeze the coal and thus heave the bottom.

In room-and-pillar work in this mine an endeavor is made to keep the breaklines parallel to the "surface seams." This cannot always be done, however, because these cracks do not always run in the same direction. As a result the breaklines in different parts of the mine are not maintained parallel. As M. D. Bouldin, general superintendent of the company, puts it, "Judgment, based on changing conditions, and no one fixed theory found in books, must be followed in this matter."

Thus far no attempt has been made to use the loading machine in drawing pillars, though a trial of its effectiveness in this work is contemplated. The method planned is to drive a 15-ft. place through a room pillar, leaving a 12-ft. stump to be mined in two face cuts by undercutting and loading machines.

Mr. Bouldin is a strong advocate of short rooms, insisting that the rapidity with which such places can be recovered reduces the cost of cleanups and the maintenance of timbers and track, and thus more than offsets the expense of driving room entries close together. Where the rooms are driven short, loading machines lose less time in moving from room to room and in waiting for mine cars to be shifted. In this mine a loading machine will move without difficulty from the face of one room to another, a distance of about 500 ft., in 12 min., including the time required to mount and dismount the track wheels.

Rooms are driven 300 ft. long and 26 ft. wide, on 70-ft. centers. In order to obtain more coal from one room cut and to reduce the number of times a loading machine must be shifted, it is planned in new territory to drive rooms 36 ft. wide on 70-ft. centers, without changing their length. Room and track layouts also are so designed as to give the loading machine a fair chance to load coal. Permanent track will be laid with 40-ft. rails, well-ballasted and bonded, and temporary track will be built of 20-lb. rails on steel ties. Room curves will be turned on 30-ft. radii to facilitate the movement of the machine. Three rooms, and perhaps four, will be assigned to one loading machine.

Crosscuts are to be driven in each pillar at intervals of 60 ft., in the last of which, or that nearest the face, track will be laid for the storage of mine cars; empties on the left and loads on the right. A 6-ton gathering locomotive will be assigned to each loading machine and will never be required to travel more than 60 ft. from it when both are working in a room. While the loading

Fig. 4—Face in Eagle Bed Shot Down Ready for Loading

This coal goes to byproduct ovens. Consequently, aside from the expense for labor and explosives entailed by heavy shooting, a large percentage of slack is not objectionable.

Fig. 5—Each Loader Has Its Locomotive

When rooms are short the locomotive may push a trip in and pull it out depositing the loaded cars successively upon the straight entry track.

machine is moving from one room to another, the locomotive will take a loaded trip to a sidetrack on the main entry and return with a trip of empties.

In conjunction with the crosscut haulage system, if feasible, or separately otherwise, it is further proposed to use a double track at the face of each room. These two spur tracks will be connected with the permanent room track by a diamond or double-throw switch. This track arrangement is shown in one of the accompanying illustrations. The entire section is assembled as a unit. Its rear end can be clamped readily with a sliding fit to the rails of the room track. It is shifted by loosening the rail clamps and attaching the section as a unit to the loading machine by means of a chain. With an arrangement involving either or both of the layouts already described, the company hopes to get 140 tons per machine per shift. After methods of loading and haulage are perfected, the No. 4 mine will be worked mechanically, this, of course, requiring the installation of additional machines.

#### DOUBLE TRACK AT FACE QUITE HELPFUL

The double-track scheme should be ideal for use in wide rooms requiring little timbering. A locomotive can shift four mine cars or more from one track to another, keeping an empty car available at all times for filling at the end of each track. While the machine is loading the last car in the trip, the locomotive can replace the loaded cars with empties. Under exceptionally strong roof, free of drawslate, as many mine cars might be handled in a single trip as are required to hold the coal produced by one cut.

The haulage method in use at present is that of backing a trip of empties into a room, loading the car nearest the face, pulling the trip out of the room and dropping the loaded car onto the straight track of the room entry, then backing the remaining empties into the room again, and so on. While the last car is being loaded the locomotive makes a trip to the sidetrack with loads and returns with empties. Rooms must be short and the tracks in them kept in good condition to justify this method. At best it is not as satisfactory as either of the arrangements described.

In the Imperial No. 4 mine the problem of shooting the coal in such manner as to facilitate the efficient

use of machines has not been solved. In this operation the No. 2 Gas bed has an average thickness of 5½ ft. It is clean and does not carry the thick parting that occurs in some localities in this measure and in the Eagle bed that lies below it. From 2 to 4 in. from the bottom is a 4-in. band of tough woody coal, scarcely fazed by the bits of an undercutting machine. The coal is undercut below this band. The general practice of the district when shooting this seam for hand loading is followed. One center and two rib shots are used by which the bulk of the coal is adequately dislodged. The bottom band, however, falls flatly upon the mine floor. It usually is broken into such sizes and shapes as can be handled by hand but not by machine.

For this reason, where the coal is loaded mechanically, three light shots are used to break this band into small lumps before the shots above them are fired. The bottom shots, if charged sufficiently to accomplish the purpose for which they are intended, together with the roof shots, make more than the usual quantity of slack. This coal can be correctly shot only by cutting above the hard band. The objections to this method of shooting are obvious, however, if the recovery of this band of coal is desired.

The best record yet made for a single 8-hr. shift is 136 tons. Over a period of 104 full-time working days the machine loaded an average of 112.5 tons per 8-hr. shift. This average output was computed by multiplying the average hourly output over this period by 8. It includes delays due to minor adjustments of the machine, and those resulting from moving the machine and shifting mine cars but not protracted delays.

Nine men will cut and load the tonnage mentioned. The loading machine runner has two helpers. It is reasonable to suppose—as was pointed out in the description of the use of loading machines at the mines of the Kingston Pocahontas Coal Co.—that the services of one or both of the helpers may not be needed, after mechanical loading has been thoroughly systematized.

Two utility men lay track, set timbers, load bugdust and drill shotholes under the direction of the shotfirer in the rooms loaded out by machine. A crew of two men on a 6-ton locomotive is also assigned to the loader. Though mining-machine men are paid by the ton, on a man-day basis the labor of one man can be charged against the loading machine, for a crew of two men can cut twice as much coal in one shift as can be loaded out by one machine in an equal period of time.

Fig. 6—Tipple at Burnwell, W. Va.

Monitors are used to lower the coal from the upper headhouse, or that serving the No. 2 Gas bed. Coal from the lower headhouse, which serves the Eagle bed, is lowered by conveyor.

# Mine Safety Due for a Boom in Illinois When New State Council Sets Pace for National Drive

St. Louis Meeting Called by National Safety Council Hears Two-Day Program of Discussion from Rock Dusting to Death by Gas—Hundred Mine Men Want Whole State United!

**M**INE SAFETY may take a boom in Illinois. A hundred coal-mining men spent two days talking about it in the Statler Hotel in St. Louis, Mo., June 25 and 26, and wound up by laying the groundwork for the "Illinois Council of Mine Safety," an organization that is aimed to lead the country in mine-safety effort. The St. Louis meeting was engineered by the National Safety Council's mining section and brought together coal-company officials, mine-safety engineers, Bureau of Mines field men and regional representatives of the National Safety Council.

The proposed "Illinois Council of Mine Safety" is intended to have a broader scope than the St. Louis meeting. It is to draw together every element and organization that ought to be interested in making Illinois mines and Illinois miners safer. D. D. Wilcox, superintendent at Gillespie, Ill., for the Superior Coal Co., who presided through part of the meeting, is inviting a representative list of men to organize the new state council and project it next fall. Such a council is expected first to unite everybody in a great and continuous safety campaign, to generate enthusiasm for it and to lead the way for a national mine-safety council soon to be created in state sections by no less an authority than the President of the United States.

C. L. Colburn, of the U. S. Bureau of Mines, proposed that something of the sort be done so as to continue the interest that the St. Louis meeting aroused, and W. D. Ryan, also of the Bureau, actually put the state council idea into words and moved that the words be crystallized into action. And it was done.

The St. Louis meeting gave opportunity for four sessions at which many mine-safety problems of haulage, rescue, explosion prevention, safety training and medical phases of mine care were discussed in competent papers. The discussion ranged from rock dusting and ventilation down to the exact method by which black-damp kills a man, with many features between, including two noon luncheons and a picture show. W. H. Cameron, managing director of the National Safety Council, ran the first day's sessions and Mr. Wilcox those of the second day.

## ALTOGETHER TOO MANY HAULAGE ACCIDENTS

Seeing that about 35 per cent of accidents in mines are haulage accidents, some changes ought to be made in haulage methods, Ralph D. Brown, superintendent for the O'Gara Coal Co., told the conference. He recommended first that rolling stock be of a type fitted for

its job and that it be inspected regularly by someone, probably the bottom boss. A proper choice of men for haulage work also is important. Motormen and trip riders should be selected from among men whose youth, activity and sobriety qualify them for the work. Nor should any man ever be put to hauling coal without careful instruction in his job. They should be men who will accept the safety doctrine. And their bosses should set them, and every other man in the mine, an example in safe conduct that cannot be overlooked.

As for making track and roadbed do their bit for safety in haulage, Mr. Brown urged that the old easy-going idea of letting a track take care of itself be

forgotten. Haulageways should be as straight as possible and, of course, level, and should be carefully maintained at all times. Concrete roadbeds under main haulways have proved economical in the mines. Entries ought to be clear of rubbish and the side clearance of the cars should be ample. Mr. Brown would establish and enforce speed limits for trips. Man trips should

never exceed six miles an hour. Storage-battery locomotives are safest for gathering work where cars are not larger than 2½ tons capacity.

Mr. Brown would have every car blocked at the face to prevent its rolling away and would have derails at the lower end of every grade parting. In all mines where there are any grades of consequence he would have a pointed iron drag at the tail of every trip to act as an automatic brake in case the trip gets split. Where mule haulage is used he solemnly recommended that the bosses insist upon good treatment for the mules. "A mule never forgets an insult," said he, "and vengeance is certain."

## O'GARA MINES HAVE ONE BOSS TO FIFTY MEN

In the discussion that followed, Mr. Brown declared that the best way in any mine to promote safety is to inculcate the idea by personal enthusiasm on the part of shift bosses. They are the men closest to the employees, and if each boss has no more than 50 men he can give each one some individual attention. That is the O'Gara arrangement, and in addition, the company has two safety inspectors ranging through the mines all the time. Electric lights underground also are important. The O'Gara company has them at every door, switch and curve on the haulageways.

Accidents in mines cost about \$20,000,000 every year in this country, Alexander Miller, of the U. S. Bureau of Mines station in Vincennes, Ind., estimated: of this

## SAFETY ENTHUSIASM AT ST. LOUIS

**A**LLEXANDER MILLER says we know pretty well the causes of accidents and how to prevent them. Now it's merely a case of getting down earnestly to the work of accident prevention. And yet there's always something new to say and learn. The St. Louis meeting proves that, if you need to have it proved.

about \$8,400,000 is assessed against companies for fatalities and \$11,000,000 for non-fatal accidents. But we pretty well know all the causes of accidents and how to prevent them, so now it is merely a case of getting down earnestly to the business of prevention. The best weapon against accidents is personal contact between safety bosses and their men.

Mr. Miller traced the development of safety training and mine-rescue work by the Bureau of Mines from its beginning early in this century, down to the present with its ten mine-rescue and instruction cars and its record of having trained 26,126 men in the use of the self-contained oxygen apparatus. He described minutely what should be done at a mine after an explosion and just how rescue work should proceed.

In the discussion on training men in safety, the point was made that some special little recognition ought to be paid safety men by their companies, if it is no more than giving an annual dinner to those who complete the safety-training course of the Joseph A. Holmes Association. This would make the safety men recognized by every one around the mines. It was suggested that

**Appearance of Roadway Before Rockdusting**

This same roadway, which is in Indianola mine, is shown on page 46 as it appeared after it had been rockdusted. However, the floor of this roadway as shown here was covered with rock dust when the photograph was taken, for the finest dust from nearby rockdusting was carried by the current and deposited on the floor.

as foremen and mine managers are so important in making a mine crew think safety and as these men so often lose interest in safety work as soon as they pass their necessary examinations, they ought therefore to be required by law to take a safety examination every year.

#### SO WELL SOLD ON SAFETY THEY STEAL EQUIPMENT

C. F. Anderson, mine manager for the Valier Coal Co., had a puzzle to be solved. Every time his company equipped first-aid stations in the various parts of the mine for emergency use, within one single day, the equipment was all stolen right down to the wooden cabinet and the stretcher. Those were too big to go in a pocket or a dinner bucket. D. D. Wilcox, superintendent of the Superior Coal Co. had an answer. Said he:

"There always will be thieving. We lost as much safety equipment as anybody, so long as it was public property and free of access to anybody in the mine. So now we designate our safety men and post their names and locations on the nearest telephone or section office. When a safety man is called, he goes to his own

individual lock box in the underground hospital where all the first-aid equipment is kept. This makes him personally responsible for his outfit. Periodic inspections of his box also help to make him keep the equipment intact and in good condition."

Rock dusting, of course, was an absorbing topic. The main paper on this subject was one written by Thomas J. Fear, general superintendent of the Inland Collieries Co. of Indianola, Pa. Mr. Fear was not present. In his absence W. D. Keefer, new director of industrial safety, National Safety Council read his paper. His warning that an explosion can be propagated on only three hundredths of an ounce of pulverized coal in suspension per cubic foot of air, brought home to the conference the danger of such coal dust. His recommendations for reducing it got close attention. He recommends rock-dust stemming for shot holes, saying that it reduces the quantity of explosive needed 10 to 30 per cent and increases the proportion of lump coal 10 to 25 per cent.

Mr. Fear recognizes the value of sprinkling in mines and humidifying air, but each is decidedly uncertain in the degree of protection it affords. Therefore, he urges rock dusting. The Bureau of Mines experiments show coal dust to be explosive when it is fine enough to pass through a 20-mesh screen and that rock dust to nullify its inflammability should be not more than 2 per cent combustible and fine enough so that all will pass through a 20-mesh and 50 per cent of it through a 200-mesh screen.

At Indianola the first machine for dusting applied 80 lb. of dust per minute through a 2-in. nozzle at 60-lb. air pressure. It had a stationary Y-shaped outlet which did not secure uniform deposits of the rock dust in cuts, manholes and such places. The machine now used has a 4-in. movable nozzle and a maximum capacity of 10 lb. of dust per minute. The velocity of the rock dust sweeps the lighter coal dust from ribs and roof. This is not deposited on roof and ribs further along but is apparently weighted down by the rock dust and falls to the floor. Such dusting now gains a credit for mines practicing it in Pennsylvania from the state compensation rating bureau.

#### LESS THAN CENT A TON DUSTS MINE

During the past month in the Indianola mine, 46,000 ft. of entry were dusted with 105,400 lb. of dust, averaging 2.3 lb. per lineal foot. The total cost was \$505.73 or \$0.007 per ton of coal mined. The deduction thus won on insurance costs was about \$0.0015 per ton. Dust cost \$4.40 per ton and handling is charged at 50c. per ton. The cost of this first dusting is \$0.011 per foot, but repeated dustings each three or four months it is estimated will cost between \$0.003 and \$0.004.

Mr. Hayden, of the Cosgrove-Meehan Coal Co., wanted to know how much moisture stone dust in a mine will absorb out of the air current. James Towal, of the E. I. du Pont de Nemours Co., estimated it at 2½ per cent. Superintendent F. F. Green, of the Valier Coal Co., one of the active dusting companies in Illinois, said the natural moisture content in freshly pulverized shale makes it stick to roof and ribs to greater depth than coal dust.

From this the discussion veered off into an argument over the increase in blowout shots in recent years over "the good old days." Some blamed it on poorer supervision of miners but most of the disputants laid it

simply to the greater present-day ignorance of the so-called miner in this country and his unwillingness to snub his cut as required, preferring to blow it all to pieces with overcharges of explosive. Nobody had any remedy for this overcharging except that all loading and shooting of holes should be company work, done by a few skilled men in each mine who can be properly supervised.

The conference lunched in one of the large private dining rooms of the hotel at noon of the first day, and saw the Peabody memorial film, "When a Man's a Miner," shown by the Bureau of Mines. These mining men silently and interestedly watched the full four reels of the story of "Lucky" Burns, detecting but one technical flaw and that a slight one: One of the rescue teams traveled much faster than the prescribed speed in exploration. Otherwise the picture pleased them, though it was freely remarked that the dramatic moments rather missed fire.

In the afternoon session Superintendent Wilcox, of the Superior Coal Co., read a paper on ventilation and dust control. He declared that at many mines a heavy expense from ventilation leaks and improper disposition of air currents is sustained without that fact being realized. He reviewed many of the common causes for those losses, such as sharp turns and sudden restrictions in aircourses which might just as well be removed. In discussing stoppings, he said his company had discarded ash and cement blocks as too porous and now has standardized on concrete blocks, set deeply into roof, ribs and floor.

#### JUST A LITTLE GUIDING AT FOOT OF DOWNCAST

The volume of air input frequently is 100 per cent in excess of mine requirements yet the men at the faces do not get enough air. There may be too much space allowed—or too little around the top of the downcast, or the cutoff may be in the wrong place, or the air may be required to make too short a turn. At one of his own mines, the right-angled turn where the downcast met the bottom set up eddies of various kinds and greatly reduced the delivery until a V-shaped contrivance was built into the bottom with its apex upward. This forces the air both ways and practically eliminates eddies. Today, in one of the Superior mines 200,000 cu.ft. of air per minute is delivered by an 18x6-ft. fan with a water gage of 0.7 in., the mine spreading more than a mile in each direction.

James Towal, of the E. I. du Pont de Nemours Co., discussing the safe handling of explosives said it is unfair to expect the powder companies to replace steel powder kegs with other material just to keep foolish miners from exploding them by driving in the bungs with picks. If powder got the respect to which it is entitled there would be no such accidents. He laid down a few rules for handling explosives at the face such as: Carry no matches or open lights, load shotholes gently, use electric squibs, tamp shotholes out clear to the face of the coal and shoot one hole at a time with a battery.

#### RECLOSING CIRCUIT BREAKERS ON SMALL LINES

"Six bushels of advice on preventing accidents from electrical equipment," a paper written by L. C. Ilsley, of the Bureau of Mines, was read by E. J. Gleim, of Pittsburgh, Pa. Each "bushel" dealt with one problem such as electric-shock prevention in which he advised grounding the frames of all surface motors, guarding all live or moving parts and leaving ample

clearance around all feeder lines. The other "bushels" dealt with gas ignition, dust ignition, explosives hazard, electric haulage and mine-fire preventions. Mr. Ilsley's paper drew some fire by stating that automatic reclosing circuit breakers are safe only on main lines and not on small feeder lines. Mr. Gleim said he thinks Mr. Ilsley believes there is danger of such a breaker closing when the "short" is brief and less than a certain load.

#### MINERS THINK SAFETY THE OPERATOR'S FAD

The essential work of reaching the miners with the safety doctrine can be done better by the Bureau of Mines through its Joseph A. Holmes Mine Safety Associations than by the National Safety Council which called the St. Louis conference, W. D. Ryan declared. He is a Bureau of Mines safety commissioner but he insisted there was no animus against the National in his words. He merely insisted that the National has not the equipment nor the talent to do the bedrock work among miners. So he urged close co-operation between the National and the Bureau, each doing its own special service.

"There ought to be some miners here at this meeting," said he. "They are the men about whom we are

Laying the Dust on Thick with Projector

Scene in Indianola Mine, of Inland Collieries Co. There is a certain distance at which the nozzle of the projecting equipment should be held to get the best results.

talking. They are the fellows over whose safety we are worrying. They should be given prominent places upon this program instead of putting on four Bureau men as was done."

It was replied that all Holmes chapters in Illinois and President Frank Farrington of the Illinois miners had been invited and that Vice-President Harry Fishwick had tentatively accepted because of Farrington's illness; but Mr. Ryan reported talking to Fishwick only the night before in St. Louis, and Fishwick had said he wasn't coming.

"Then it's the miners' own fault," said J. S. Anderson. "They evidently were invited and they apparently regard the meeting as something the operators have concocted and which, therefore, should be scorned." He complained that this attitude of the union is what makes it hard to train safety men. When a Bureau car comes into a mining town in Illinois to conduct classes, only 15 or 20 out of possibly 800 union men attend, and these do it rather warily because they are liable to be suspected by the union as trying to curry favor with the company. In any event miners listen more readily

to the orders of the union than to those of their employers.

Mr. Ryan, in his address, "What the Joseph A. Holmes Safety Association is Doing For Accident Prevention," stated that in spite of the financial losses of \$20,000,000 or more annually to coal operators through accidents, many operators will not help in the safety work. One in Montana even refused to pay a safety-trained miner for a day he lost taking care of a buddy hurt in the mine, who otherwise would have died at heavy compensation cost to the company. This sort of refusal to co-operate is one of the obstacles in the way of safety.

However, Mr. Ryan also had some cases of the union refusal. He cited the Oklahoma case where the district union organization of "bolsheviks" stands by State Inspector Boyle, in opposition to the introduction of safe electric cap lamps in Oklahoma.

#### MINER IS NOT BEYOND ARGUMENT

He took issue with declarations of others that it is no use trying to educate the miner in safety. He insisted it can be done if it is tried right, for the American miner is not the ignorant roughneck he is often pictured. In 1920 it was found that 88 per cent were literate and only 30 per cent foreign born. Of these foreign born four-fifths had been in this country 10 years or more. Safety education will reach them and 75 per cent of accidents can be eliminated. He made some safety suggestions. Here they are: Use closed lights in all gaseous mines. All drilling, loading and shooting in order to reduce blown out shots should be performed by company men. No mine examiner should be allowed to use a safety lamp he can unlock. If that had been done the Hastings and Kemmerer disasters and many other explosions could have been avoided. Every miner should be required to test the roof of his place every morning before anything else is done. Permissibles should be required in all mines where there is reason at all to use them. Joseph A. Holmes chapters should be installed in every mining camp.

After hearing some bitter complaints that the Holmes chapters so often die or suffer dry rot, James Boston, safety man for the Superior Coal Co., Gillespie, Ill., laid his cob pipe on the edge of the speaker's table and said the chapter was working fine in Gillespie and he'd tell the world why. It's got to be that way anywhere if safety is going to amount to anything. The company does its part by supplying all the necessary equipment, by seeing to it no miner loses pay for time he spends in safety work and by otherwise meeting the men half way. The men are stimulated to work at this safety business and they do it. Hence there are mighty few accidents at Gillespie.

But before Boston picked up his cob pipe again, he flayed the operators of the country for not supporting safety work. Through somebody's neglect or refusal to put up money, the Huntington national first-aid contest was called off. The union didn't cancel it nor yet the Holmes associations. Someone else did. The same thing happened to the Illinois state meet to have been held at Belleville and this made the Holmes chapter at Gillespie so incensed that it is going to put on the state meet next fall under its own auspices and has raised most of the money already from union organizations and individuals.

There were some queries as to just what the Joseph

A. Holmes Mine Safety Association is, anyway, and how to organize chapters. So C. L. Colburn traced its history since it was started under the protective wing of the Bureau of Mines in 1916 as a memorial to the first director of the Bureau in place of erecting a cold monument in Washington. Some twenty-four organizations besides the Bureau joined in forming it. There are now ninety-six chapters in mining towns, about sixty of them virile.

#### HOW ASSOCIATION WORK IS FOSTERED

Any operator or union local can organize one among any group of miners and get the assistance of the headquarters in Pittsburgh, Pa. In Illinois the state department of mines and minerals or any state inspector will help. Dues of from \$10 to \$50 a year, depending upon the size of the chapter, are paid by each chapter, none of which is spent for salaries or traveling expenses by any of the national officers or directors—a list which includes the Director of the Bureau as president, and officials of the National Safety Council, the United Mine Workers and other organizations. The headquarters issue buttons to all members, many safety bulletins and instructions, sends out speakers and otherwise fosters the work of the chapters. It is now broadcasting safety talks by radio from Pittsburgh.

Mr. Colburn said safety is like a business: When it is properly directed it pays. Dividends go not to stockholders alone but to companies, employees, their dependents and everybody else who is interested. Of course accidents produce compensation in money to men who get hurt, but does money pay for the lost arms and legs and eyes? How much finer humanitarianism it is to save those arms and legs and eyes by safety practice!

To really practice it, he said, not only must a mine property be made physically as safe as possible and equipped with the necessary safeguards, but, more important still, company officials must be enthusiastic about safety and preach it by word and deed, and employees must keep up an aroused interest even after they have been instructed in safe practice. This usually can be done by giving them active parts to play in some phase of safety work or in the Holmes Chapter's activities. It was here that Mr. Colburn proposed the Illinois state safety council, the plan for which was started before the conference adjourned.

#### OXYGEN FILTERS INTO HEMOGLOBIN

Just what do mine gases do to the human body? How is it that they kill? In A.B.C. fashion and most interestingly Dr. H. G. Bristow, professor of chemistry at St. Louis University, talked about this subject, referring especially to common mine gases such as carbon dioxide and carbon monoxide.

He began by explaining that a man inhales air in order to deliver oxygen into the blood stream where it is carried in chemical combination with the hemoglobin or red matter in the blood corpuscles. In the lung tissue it filters into the hemoglobin much as water at different levels, separated by a finely perforated partition, would run from the high-level side into the low until equilibrium is attained.

So long as the blood coming into the lungs is low in oxygen, the oxygen from the air will continue to be absorbed. Then the blood carries it to the tissues of the body structure where the oxygen content is low and the carbon dioxide (caused by muscular effort)

**A Dust-Coated Mine Haulageway**

This is the roadway shown in the illustration on page 43. Only the form of the coal surfaces remain after rockdusting. The coal is so covered with limestone dust that it looks just like rock. A drill or a pick almost would be needed to convince one that the coal thus disguised was coal and not rock. Yet the coating can be rubbed off readily by the hand and is so loose that a blast would not fail to dislodge it.

is high. Here the carbon dioxide runs into the blood and oxygen into the muscles until equilibrium is attained again. Thus the process goes steadily on so long as the air a man breathes has an oxygen content of at least 12 per cent. It normally is about 20 per cent.

But if the man's a miner and runs into carbon dioxide in the mine, the air he breathes may have less than 12 per cent of oxygen. Then it cannot deliver oxygen into the blood. There is so much carbon dioxide present that his lung air cannot remove from the body the carbon dioxide the blood has brought in. The result is suffocation in short order.

If the man is resuscitated, however, his recovery is rapid, for the lungs contain no less than 100 sq.yd. of contact surface for the passage of oxygen and carbon dioxide between blood and breath and a large volume of both can be transferred within a few minutes. Normally a man inhales 1,200 quarts of oxygen and exhales 100 quarts of carbon dioxide in a day of average activity.

The other gas, carbon monoxide is more dangerous than carbon dioxide because, when it filters into the blood it forms an absolute chemical union with the hemoglobin of the blood and is not unloaded at the other end of the line. It remains in combination, thus effectively putting the red corpuscles out of business. They can neither carry in oxygen nor carry out the gas of worn-out body tissue.

The hemoglobin absorbs carbon monoxide 300 times as readily as it does life-giving oxygen, so that a trace in the lungs soon saturates all the red corpuscles in the blood, even though there may be much oxygen present. As little as six parts of carbon monoxide in 10,000 parts of air makes a man drowsy in half an hour and 50 in 10,000 produces unconsciousness in that time. Higher proportions such as are encountered after mine explosions kill a man in a few breaths.

#### **JUST SUFFOCATED BY GAS, NOT POISONED**

"However, these gases are not poisonous," said the doctor. "It is a common fallacy to think so. They kill merely by the mechanical action of preventing the body from getting rid of its own waste matter through the breath. A man is not poisoned to death by them at all. He is just suffocated. After resuscitation he is left without any detrimental after-effects.

"There are only a few poison gases made in mines. About the only one ever encountered, is what the miner calls 'stink damp.' It is a combination of hydrogen called hydrogen sulphide and certainly is well named a 'stink' gas. It advertises its presence so well and is in such small concentration in the air that a man is almost always able to get away from it. Also it acts slowly although poisonous, and altogether is no menace at all compared to the non-poisonous gases."

#### **ANIMALS IN MINES CAUSE INFECTION OF WOUNDS**

It was remarkable how much interest Dr. J. B. Moore, of Benton, Ill., could arouse in the subject of "Infections from Wounds." After considerable experience in the heart of the southern Illinois coal field he declared that it is fallacious to believe that the sulphur in mine water in any way promotes infection. As a matter of fact sulphur is an antiseptic. Mine water is by no means as poisonous as many mining men think. Even water in a long abandoned mine ought not to be infectious even though timbers may have decayed and fermented because there are few harmful bacteria in wood and many helpful kinds. It is usually animal matter that makes mine water dangerous. Animals in mines always add to the likelihood of infections in men's cuts and injuries. Thus the motor-haulage mine is safer in this particular than the mine in which the mule is used.

Dr. Moore had much to say about the value to a miner of clean clothes next his skin, though the outer garments may be filthy. He condemned the use of any sort of soiled cloth for temporary dressing of wounds or slight skin injuries. The mine bathhouse makes the skin of today's miner far cleaner than that of the miner of long ago and thus greatly reduces many health hazards.

A discussion of eye injuries and first-aid treatment roused almost the whole conference to speech. The doctor said any man who gets even a slight eye injury should drop his work and go to a doctor at once for infections can set in within a few hours. Many a good eye has been sacrificed because a buddy attempts in all kindness to remove some foreign matter from a miner's eye with the corner of a dirty handkerchief. M. L. Felmer said southern Illinois coal, for some reason as yet unknown, seems to have a peculiar power to infect eyes.

#### **FIRST-AID MEN SHOULD NOT TREAT EYES**

James Boston remarked that at Gillespie good first-aid work appears to reduce trouble from eye accidents. This roused Dr. Moore who is absolutely opposed to the first-aid men at mines treating slight eye injuries. There is too great danger of the patient regarding such temporary treatment as permanent. Many unsuspected infections have developed from such treatment and run into dangerous stages before a doctor ever sees them. Too often mine first-aid kits become contaminated from improper care. This is one reason why the local doctor often is blamed for failures to save eyes that he treats. After an ulcer gets a foothold even a specialist seldom can restore the eye without blemish and often cannot save the sight. Such ulcers can develop overnight. Therefore, Dr. Moore said, no man ought ever to go to bed with any eye injury untreated by a competent physician.

The conference ended late in the afternoon of June 26, its second day.

## What Does the Power That We Needlessly Waste Cost Us?

Abuse of Electric Service Frequently Costs More Than Its Use—Most Abuses Corrected by Actual Meter Readings

BY CHARLES A. SWARTZ  
Springfield, Ill.

AT A LARGE number of mining operations, where most of the houses are occupied by mine workers or salaried employees, it has been the practice to supply—either without charge or else on a flat-rate basis—the electric energy used for light and other purposes in these houses. With no check imposed on the use of the service, the shiftless and irresponsible elements of the communities naturally let the electric lights burn without regard to their proper use or to company interests.

Where electric service was supplied free, the whole burden of such extravagance was borne by the owning company. But where the flat-rate system prevailed, waste of current, by increasing the expense to which the company was put for supplying the service, compelled an increase in the flat rate charged. This increase naturally had to be borne by the better element in the community as well as by those whose wastefulness brought it about.

The inequity of such a system became apparent to the management of many mining companies and has resulted in the introduction of the system which experience in the general industry of supplying electric light and power to the public has proven to be the only just and practicable method of creating true service economy. This is the system of measuring the energy supplied to each separate customer and basing the charges made to him on the individual energy consumption indicated by periodical meter readings.

### GENERAL SOCIAL ADVANCE FOSTERS METERING

The introduction of this system of metering the electric energy supplied to the homes of miners and other workers living in communities where the furnishing of electric light and power is a service performed by the chief local industrial plant, has, in a measure, been accelerated not only by progress in plant management but by the general social progress of the entire country. As has been outlined the principal factor in making the system of supplying electric energy gratis and unrestricted, or of furnishing it on a flat-rate basis, too expensive to continue, was the shiftless habits of some of the people in the communities served. The effect of such extravagance was, of course, mitigated by the economy in electric service characteristic of the better class of the community. However, with the increasing development and adoption of electric flat-irons, washing machines and all manner of electric household appliances, this better element—because of superior industry, thrift and self-respect—aspired to the use of these devices and began rapidly to increase its average consumption of electric energy. Consequently, such aspirations, though laudable, added substantially to the burden borne by the employing industry supplying the free or flat-rate electric service.

Because of these conditions, as has been stated, numerous progressive coal-mining companies have installed watt-hour meters in their company houses.

Fig. 1—Curves Showing Waste Reduction

This shows how rapidly the needless waste of electric current decreases when the quantity actually consumed is once known. So long as anyone receives current gratis or on a flat rate there is small incentive to save "juice."

Many interesting results followed. For instance, one superintendent who had been paying a flat rate of \$1.50 per month found himself presented with a bill for \$18, based on a nominal charge for energy shown to have been actually consumed during the first month after his meter had been installed. As may be imagined reasonable economy in the use of electricity in his household quickly came about after this mine official had paid his first bill.

Whether the excessive use of free electric service by such officials arises from an indifference comparable to the shiftlessness of a certain type of miners, or from a feeling on the part of the former that unlimited use of such service is a perquisite properly appertaining to their position, such instances establish the fact that watt-hour meters can be quite properly placed on the premises of all classes of mine employees. The extent to which extravagant use of electric energy declines on installation of electric meters is illustrated by the fact that one company, after being forced by such extravagance to install these instruments found that after such installation 15 per cent of the users did not consume enough electricity, figured at 8c. per kilowatt-hour, even to equal the company's minimum charge of 75c. per month.

Further details of the workings of meter installation toward a reduction of waste is illustrated by the accompanying curves. The company from whose records these curves were made was active in both manufacturing and coal mining in a certain town. As it owned the principal local industries, it supplied electricity on a flat-rate basis to all the houses in the community.

It was decided to install watt-hour meters. The placing of these instruments extended over a period of three years. In Fig. 1, the curves plotted show average

kilowatt-hour consumption per installation at corresponding periods in successive years as the metering of consumers' circuits progressed. The points upon which each curve is plotted represents yearly periods. Fig. 2 is a composite of the four curves and makes evident the trend of energy consumption per connected user, as the percentage of metered houses increased. The downward slope of this curve is significantly indicative of the economy effected through the use of these meters.

#### METERING ALL HOUSES INCREASES ECONOMY

This economy can be summarized by stating that at the beginning of the period under consideration there were only 76 meters installed among 382 houses served, with an average monthly consumption of 220 kw.-hr. per house. After three years, 709 out of a total of 712 consumers were on a meter basis and average monthly consumption had fallen to 62 kw.-hr.

Even with watt-hour meters installed, the determination of an equitable charge for electric energy supplied by coal-mining companies to the homes of their workers is not always easy. For instance, there is the problem of floating population. Some mining companies install meters only in houses occupied by salaried men, and other classes of consumers whose interests are regarded as permanent.

By subtracting the aggregate quantity of energy passing through these meters from the total output of current shown by the totalizing meter registering the energy supplied outside the company plant, the quantity of current furnished the miners is determined. A charge is made in proportion to this total quantity of energy, the charge being divided among the whole body of miners.

As an inducement to economy, a charge for service is made to the metered consumers only when the energy used passes a certain figure. As a result, power consumption is kept within close bounds. For a consumer in this class to run over the quantity given free

Fig. 2—Curves of Fig. 1 Combined

With no yardstick to serve as a measure anyone may consider that he is saving in his use of electric current when, as a matter of fact, he may be highly extravagant. Installation of a watt-hour meter immediately furnishes the householder with a means for comparing his current consumption from month to month and enables him to judge for himself whether he is frugal or extravagant.

Fig. 3—Direct-Current Watt-hour Meter

It is useless and illogical to demand economy in power production and permit unchecked extravagance in its use. Installation of an instrument such as this in the supply line or power circuit prevents "saving at the spigot and wasting at the bung hole," as electric current too often is handled at mining plants.

is exceptional. It is estimated that the power consumption among this class is now hardly half what it was before the installation of meters.

In order to drive home to the miners the need of economy in the use of electric current in their unmetered houses, the flat rate was increased 60 per cent. The miners were told that the new rate would be reduced as soon as they became more economical of the service. Up to the present time, however, no evidence of such economy has become apparent.

Apropos of economy in the use of electric energy in the homes of company employees, it seems rather inconsistent to insist upon such frugality without taking effective steps to accomplish similar savings in the company's plant itself. Power costs in coal mining are appreciable, and the proper use of watt-hour meters can effect substantial savings whether the energy used is purchased from a central station, or generated at the mine.

It is of little use to require the plant engineer to make power from bone coal or "dirt and dust," in order to save marketable fuel for sale, if the economy thus effected is offset by waste of the power generated. It is of little use to install carbon-dioxide recorders and other up-to-date boiler-room instruments for checking up economy in power production, unless suitable instruments are also employed for checking power consumed.

Some of the places where power may be wasted are the haulage circuit, the breaker or tippie drive, the ventilating fans, the coal cutters, the air compressors, the electric mine pumps, and the like. If power is purchased, it is certain that the central station company supplying that power has a meter on the feeder through which energy is transmitted to the mining plant. It is, therefore, equally as important that the mine operator should have his own meter on his end of the feeder so that he can check up intelligently the power bills his company must pay. If the bills show that his company is being charged for more electric energy than the watt-hour meter indicates was consumed by his plant, there is obviously a difference between the meter on his end of the line and that installed by the power company. When such differences occur, both meters should be tested and the trouble rectified.

In order to determine the cost of the various mine

operations, the cost of power consumed in them must be charged into the total figure. Unless watt-hour meters are installed on the various circuits supplying such power, it is impossible accurately and conveniently to determine these power costs. Neither is it possible, without such meters, to check up and detect power wastes that may cause appreciable losses.

In this connection, note the extensive employment of watt-hour meters on street cars. Such meters so installed provide a continuous record of operating economy. By simply dividing the power consumed by the mileage multiplied by the load, the efficiency of both car and driver can be easily determined. Knowing that such a check is placed on their work, motormen are more careful than they would otherwise be. It is estimated that from 10 to 20 per cent saving in power is thus effected in street-car operation.

The same principles apply to the operation of electric mine locomotives. Progressive mining companies are already demonstrating that similar economy can be affected in the department of mine transportation.

Still another advance toward power economy obtainable from the use of watt-hour meters on mine locomotives can be gained by installing a totalizing watt-hour meter on the main haulage-circuit feeder. By subtracting the aggregate energy consumption of the locomotives from the total energy supplied the haulage circuit, as shown by the haulage-feeder meter, any excessive absorption of energy by reason of poor rail bonds, feeders of insufficient cross-section or equipment in poor condition, becomes immediately apparent.

Thus, motorman efficiency, locomotive efficiency and the general efficiency of the entire haulage system are at once collectively and individually indicated by the data afforded through the use of these various meters.

Similarly, watt-hour meters on light and power circuits in and around the coal mines can be made to yield substantial dividends on a moderate investment. There are, of course, various types of such meters respectively adapted to the different conditions encountered. The manufacturers are in a position to effectively co-operate with mine operators and engineers interested in such installations.

Fig. 4—Alternating-Current Watt-hour Meter

This is a polyphase instrument intended for mounting on a switchboard. It may be used to measure either the output of a plant of the input to any particular line. Actual costs of any process of mining must remain unknown until definite records can be had of the power consumed in that particular process.

## The Miner's Torch

### When the Big Boss Goes a Visiting

THE president of a large coal mining company gave me an invitation today to accompany him on an inspection trip covering all of his mining camps and I declined with thanks. Whenever I get invitations of that kind I recall the heart aches and the disappointments brought to me and mine back in the days when I was a mining superintendent and our president, or general manager, and his friends honored our camp with such a visit. Me and mine includes not only my men but my wife and children as well.

The first ordeal of that kind that I recall came early in my married life. We had received notice from the general office that our president and some of our directors would honor us with their presence on a certain day about two weeks later. That night I broke the news to my wife and from that moment she was the busiest person in the camp.

We had a pretty fair house, as mining-camp houses go, but my wife had never been in mining camps previous to our marriage and she knew that our house and its furnishings would not reflect credit on her when inspected by the average city folk. Furthermore, our daily menu, dependent as it was on commissary variety, would hardly cause visitors from a city to wax enthusiastic about our eating; my wife reasoned that her only chance to make an impression was through her housekeeping or her cooking, so our commissary manager had to make several special trips to town for provisions before he satisfied my wife. Of course, it was useless for me to argue that she was taking the thing altogether too seriously; she had found out that I was moving heaven and earth to have the general appearance of the camp improved, and had instructed every mechanic on the job to get busy cleaning machinery.

I have had charge of quite a number of different operations in my day but I have never succeeded in getting one more nearly ship-shape than was that plant when the day for inspection arrived. And what was the reward?

While the crowd was standing at the slope mouth waiting for a trip of cars to come to daylight, a perfectly good wooden roller decided to stop turning and before the trip reached the outside the rope had worn a groove in the roller and yanked it out. Not one of the party noticed the rope or the roller until the roller was lying outside of the track and the rope was sawing grooves in the wooden ties and striking fire on the ballast. I am sure that that one little missing roller made more of an impression than anything that the visitors saw while inspecting the plant.

And what about the wife? The visitors came out in a private car and preferred to have their own chef serve lunch because, as one of them expressed it, a change of food and especially water is always risky. Not one of the visitors met my wife nor suggested that she come over to the car for the noon luncheon they had while the car was on our camp siding. Perhaps they didn't know I had a wife.

# Competition of Oil with Coal for Fuel Purposes Begins to Lose Its Edge

Increasing Price Taking Away Principal Advantage—Uncertainty of Supply Menaces Future of the Industry—High Operating Efficiency and Absence of Ashes Counterbalanced by Wear and Tear on Boilers

**O**IL IS losing the advantage in price it once had in competition with coal and its supply is by no means as sure as that of coal in this country. For these reasons Borden Covell, president of the Northern Coal Co., of Boston, sees a weakening of oil as a competitor of coal in New England and elsewhere. He reviewed the matter before the American Wholesale Coal Association convention in June.

Six or seven years ago, he said, oil came in strong against coal, mainly because oil salesmen could convince buyers of heating equipment that oil would cost them 10 per cent less than coal and that they could save the entire cost of their oil-burning equipment during the life of their very first oil contract. In the thickly settled and manufacturing districts there is enough labor trouble to make coal firing often troublesome. This, too, helped the oil man. The high coal prices of 1920 made the oil buyer feel justified in the belief that he had done the right thing when he shifted to oil. But conditions have changed. The coal man has the advantage today.

Owners of plants who think of changing from coal to oil today should make haste very slowly, in Mr. Covell's opinion. Even if the price of oil is as low as coal now, what will it be on the next contract? And how long will plenty of oil of the right quality be available?

## OILS OF MANY SPECIFIC GRAVITIES RECEIVED

"Approximately 725 billion barrels of fuel oil," said Mr. Covell, "are produced annually. Mexico contributes 25 per cent of this. Crude oil as produced in Mexico carries too low a flash point to permit its use generally. Therefore the oil is topped—that is, a small percentage of gasoline and other light oils is distilled to save the oil and produce a fuel which will flash at not less than 150 deg. This residue runs 14 to 16 deg. Baumé and will average 18,400 B.t.u. per pound. It is well to add right here that whereas in the early stages of the game oil ran uniformly, it is now quite the opposite. There are so many grades of oil coming into the market that a plant now using oil for fuel must figure on receiving oil of different specific gravities, just the same as it received different grades of coal.

"In order to give some figures on cost, we will assume as a standard coal showing 14,250 B.t.u. as received. Fuel oil is sold by the barrel. To reduce that fuel to weight, let us figure 18,400 B.t.u. per pound, 8 lb. to the gallon, 42 gal. to the barrel. These figures give 31,920,000 B.t.u. per gross ton of coal, and 6,180,000 B.t.u. per barrel of fuel oil. One gross ton of bituminous coal will be equal to 5.17 bbl. of oil on a heating-value basis, *regardless of efficiency*. In some sections steam sizes of anthracite coal are sold in competition with bituminous coal. Therefore, figuring 11,500 B.t.u. per pound for this class of fuel gives us 25,760,000

B.t.u. per gross ton, or equal to 4.17 bbl. of oil on a heating-value basis, regardless of efficiency.

"The percentage of efficiency is of paramount importance. Comparing oil as against the various types of coal, we find:

	Operating Efficiency	Barrels of Oil Equivalent to Tons of Coal
Hand firing.....	63%	4.23
Stoker firing.....	75%	4.96
Pulverized coal.....	80%	5.36
Steam sized anthracite.....	68%	3.68

"Cost of changing over from coal to oil is important. Hand-fired plants usually are small and therefore not attractive to the oil man. Stoker plants, depending on how elaborate, cost from \$16 to \$25 per horsepower. The cost of installing oil as a fuel depends largely on the size of storage required, ease of installation—regulations are very strict on this—resetting of old boilers, or the installation of new ones. Conditions vary, so that the cost runs from \$15 to \$40 per horsepower.

## EAST USES MEXICAN OIL, SOUTH-WEST AMERICAN

"The oil used for steam production in the East is essentially Mexican oil, while that used in St. Louis, Chicago and the Southwest is what might be called American fuel oil. The Mexican is a good deal heavier and conditions of feeding it into furnaces are quite different from those when American fuel oil is used. For instance, some years ago a large plant in Rhode Island ran short of its regular fuel oil and the contractors shipped to it quite a bit of American fuel oil. The plant's apparatus was lined up to use the heavy oil with a steam pressure for putting it into the furnaces considerably higher than is necessary in using the lighter oils. Therefore the waste sustained was considerable.

"The first contract made on fuel oil in New England was in the autumn of 1915 on the basis of 85c. a barrel f.o.b. cars tidewater point New England, for a term of five years. Assuming 4½ barrels of oil per ton of high-grade coal, this was equal to coal at \$3.61 f.o.b. cars shipping point.

## NOWADAYS MUST PAY MARKET PRICE FOR OIL

"When fuel oil was first introduced, contracts could be made at a fixed price for a term of years; today it is customary to base the price on the price of bunker oil f.o.b. New York as quoted daily in the New York *Journal of Commerce*. Today the price quoted is \$1.75 per barrel. Prices in Providence, Boston and Portland are 10c. a barrel higher. Therefore, if you order today, say, 10,000 bbl. of oil, the price is based on the quotation that you read in the New York *Journal of Commerce* as of that day, plus the differential charged at the various distributing points in New England, or say \$1.85 Boston. Using 4½ bbl. as equivalent to a ton of coal, this means coal at \$7.86 f.o.b. Boston. We are

asking \$5.75 f.o.b. cars Boston for high-grade West Virginia smokeless coal, or a difference of \$2.11 a ton in favor of coal.

"I have a few comparative costs of the typical New England mill burning around 10,000 tons of coal a year. An engineer went into this plant, studied the conditions as he found them, and reported to the owners that coal and oil bore the following relation in cost: Coal at \$6 per ton equals oil at \$1.58 per barrel; coal at \$7 equals oil at \$1.80; coal at \$8 equals oil at \$2.02; coal at \$9 equals oil at \$2.24; coal at \$10 equals oil at \$2.47.

"We will assume for comparison that coal today would cost this plant \$7 in its bins; therefore, it would have to buy oil at \$1.80 per barrel delivered, whereas the cost today is \$1.85 f.o.b. Boston and there is a freight rate of 25c. a barrel. In other words it could pay between \$8 and \$9 for coal and be on an equal footing with oil.

#### NOW COAL IS 30 PER CENT CHEAPER THAN OIL

"In the last five years it would seem as if there was less spread between the contract and spot prices of oil than of coal; so in this comparison oil is favored. However, during that time there were two periods when coal was difficult to obtain and consequently prices were high. On the other hand, there were two periods of overproduction in oil and prices consequently fell. A comparison of figures shows fuel oil today at \$1.75, New York Harbor, and high-grade coal at \$5.25@5.50 per gross ton at the piers, with, I fear, a tendency downward. On the basis of 4½ bbl. of oil to a ton of coal, we find oil costing \$7.43. This means coal is approximately 30 per cent cheaper than oil.

"In a manufacturing plant the value of fuel as it is delivered is not so important as the cost per 1,000 lb. of steam leaving the boiler room. Each plant has its own particular conditions and therefore study is required before proper decision can be made. It behooves the concern studying its present costs with coal as fuel against those submitted by engineers for the oil people to see first if he cannot improve the conditions under which he is burning coal without going into any heavy expenditure.

"The points usually stressed by the proponents of fuel oil are: That oil has higher efficiency, makes no ashes, is of higher capacity and can be fired with fewer labor charges.

#### OIL NOT ANY MORE EFFICIENT FUEL THAN COAL

"As to the question of efficiency it is a fact that there is little difference between a modern stoker layout and oil-fired furnaces. The error of excess air is more difficult to detect in oil combustion than in coal, thus tending to fuel waste.

"It is true oil makes no ashes, but to offset this is the residue deposited on the heating surfaces of the boiler—a deposit oily, hard to remove and highly non-conductive as to heat. Greater care is necessary in removing this deposit than is needed in blowing off the dust from ashes. In many localities today the demand for ashes, due to construction work, is so great that the cost of handling them is taken care of by those who are willing to buy them; in fact in some plants a little money is made.

"Undoubtedly the capacity is in favor of oil in plants of comparable efficiency, but this excessive forcing has ruined many boilers. The contact of the fuel-oil flame

has often cracked and burned parts of the combustion chambers.

"In hand-fired plants of a size requiring employment of many men, the labor cost is certainly higher in firing coal than in burning oil. However, modern stoker installation under average conditions existing today requires very little in additional labor costs, for under proper conditions mechanical stokers need but one fireman and one water tender for every 5,000-hp. of boilers. It is impossible for a plant equipped with fuel oil to get along with a lesser number. The labor of tending to the water levels in either installation is the same and stokers do not require any more adjustment than do the oil burners.

"We in New England have been particularly hard hit by fuel oil. Conservative estimates place the loss in coal consumption due to replacement by fuel oil at between four and a half and five million tons per year. Today the tide is beginning to flow our way and we expect to see by far the larger portion of our old customers back with us again in the next four or five years.

"The improvements each year in getting higher gasoline yields from oils make the refining process more attractive and consequently lessen the amount of fuel oil available for steam purposes.

#### OIL MAN DOESN'T WANT WINTER DELIVERIES

"Oil heating for homes has increased tremendously throughout the country, due primarily to the usual reasons—cost, scarcity and high prices. The campaign is being made almost entirely by the oil-heater man. He confines his energies to territories near the large storage centers and usually discourages the use of oil where it may be difficult to make deliveries during the winter months. Generally there is no saving in using house oil and in many cases it costs more than coal. It is attractive because there are no ashes and cellars are clean, but there is an objectionable noise and the fire risk is great. Many disastrous fires have occurred during the past winter and some fatal explosions, and we have innumerable instances of soot and oil smells invading the upper stories. We all know of instances where householders have returned to coal, but, generally speaking, this new form of heating houses will increase as better burners are put on the market. I think the use of oil for heating is in its infancy."

#### Paint Protects Concentrating Tables From Acid and Attrition

The highest upkeep item, chargeable to concentrator-table operation in anthracite breakers, is for covers and riffles. The acid water and the abrasive action of the coal tend to shorten the useful life of the covers and of the maple riffles which are nailed to them. It has been found practicable to coat the operating surface of the tables with high-grade resisting paint. In this way the life of the linoleum and wood is profitably prolonged. In the lead and zinc field concrete is being used for the table "cover." It has been used also by the Utah Copper Co., and still may be in use for that purpose. The lead and zinc companies are using rubber riffles, the Utah Copper Co. and Replogle Steel Co., however, pressing iron into that service. The first of these companies is cleaning copper ore and the second iron ore.

## News Of the Industry

### Storage Essential to Solution of Nation's Coal Problem, Says Engineers' Report

**Committee of American Engineering Council Declares It Will Eliminate Danger of Fuel Famine, Stabilize Industry, Relieve Railroads and Ultimately Cut Consumer's Coal Bill**

Storage of coal is essentially necessary as an aid to the solution of the national coal problem, the Storage of Coal Committee of the American Engineering Council declares in its report; will eliminate all danger of coal famine, stabilize industry, relieve the railroads and ultimately cut the consumer's coal bill.

The report of the committee, which was made public on July 7, sets forth that if each coal consumer will adopt the policy of annually purchasing coal on a uniform monthly delivery basis it will automatically result in sufficient seasonal storage to guarantee coal to the consumer as needed and will bring about a uniform demand for coal whereby the coal producer and carrier may establish uniform and standard production and shipment schedules.

#### Cites Hard-Coal Precedent

Confirmation of the practicability of coal storage is afforded by the anthracite industry, says the committee, which is far more stable than the bituminous, because producers, carriers and consumers of hard coal for a number of years have alike encouraged and practiced storage.

"The storage of coal also will remove the evils of intermittent operation of coal mines, frequent panicky market conditions, and coal shortages due to inability of the carriers to meet peak demand," declares the report.

The irregularity in coal production, the report continues, is largely due to seasonal demand. This seasonal demand is responsible for 47 per cent of the idle time of the coal industry. Seasonal demand also contributes to another very disturbing element, namely, the overdevelopment of mine capacity through opening too many mines. The two factors of intermittent or seasonal operation and overdevelopment are in a large measure responsible for the ills of the coal industry.

The report sets forth "a simple and practical remedy," saying that it is the coal consumer who must start the cycle that will bring about a stabilized industry.

"The amount of storage required to produce these corrective and constructive results," the committee declares in summarizing its conclusions, "is small in terms of the per cent of annual con-

sumption. For seasonal storage, from 9 to 10 per cent of the annual consumption is all that is required. If this amount is supplemented by additional reserve storage of no more than 7 per cent, the result will be an accumulation of some 83,000,000 tons of coal in storage by Sept. 30 of each year. The practicability of this amount of storage with but slight additional outlay for equipment is indicated by the fact that on Sept. 1, 1923, there was 56,000,000 tons in storage.

"Equipment has been developed and may be obtained to meet any storage situation or requirement. The cost of such equipment ranges from a few cents per ton of capacity up to \$2.50 or \$3 per ton of capacity.

"All kinds of coal have been and may be successfully stored. The cost of storage per ton, including fixed charges on equipment, maintenance and operation expense and interest on investment in coal as well as taxes and insurance, in most instances does not exceed 75c. per ton yearly. More generally it is around 50c. per ton yearly. This cost is insignificant when distributed over annual consumption.

"To increase transportation facilities to meet the peak demands resulting from the prevailing unsystematic practice in coal shipment would require an additional investment of some \$12,000,000,000. Such an investment is not justified.

#### Railroads Have Most to Gain

"The railroads have more to gain by storing coal than any other class of consumer. In general, storage should take place at the point of use, to accomplish the most in relieving transportation and safeguarding supply. In general, storage at mines is not recommended. Cars should be assigned to mines upon the basis of coal actually sold and not upon rated capacity of production."

While the report refers primarily to industrial consumers of bituminous coal, the householder, the committee says, is in a position to aid with the least cost, because no special equipment for storing and reclaiming is required and his individual investment in coal is relatively small. Householders use approximately 50,000,000 tons of bituminous coal annually, which, if placed in their bins by the end of September

### Nebraska Loses on Its Coal

Governor Charley Bryan, of Nebraska, is among those who regard coal producers as "barons." So last winter he ran a good many coal yards throughout Nebraska, undercutting the dealers. It was more or less of a success until they footed up the bills at the end of the year. Omaha, for instance, is short \$8,000 and the City Council is still wrangling over how to pay the deficit. There are about 900 tons of coal on hand, for which the city cannot get over \$3 a ton, which is less than cost, and this coal is estimated by city authorities to have depreciated about 50 per cent in value by long storage. So Governor Charley Bryan may not be so sure about coal baronism now.

of each year, would materially contribute to the solution of the coal problem.

"Federal, state, city and other civic divisions of the body politic are not meeting their responsibility in relation to the seasonal storage of coal," the committee states. "They are as derelict in regard to seasonal storage as are other users, and frequently add to a confused situation by obtaining priority orders. Public officials should take the lead, by precept and by example, in furthering the storage of coal.

"The evil practice of indiscriminate breaking of coal contracts has seriously injured the American coal industry with reference alike to production, transportation and consumption. Contracts for coal should be observed with the same good faith as universally prevails in regard to other forms of commercial contracts."

The personnel of the committee which made the investigation follows:

W. L. Abbott, chief operating engineer of the Commonwealth Edison Co. of Chicago, chairman; H. Foster Bain, Director of the Bureau of Mines, Washington; William Hutton Blauvelt, consulting engineer, New York City; W. H. Hoyt, chief engineer of Duluth, Missabe & Northern Ry., Duluth, Minn.; William J. Jenkins, vice-president and general manager of the Consolidated Coal Co. of St. Louis; David Moffat Myers, consulting engineer, New York City; Prof. S. W. Parr, University of Illinois, Urbana; Dean Perley F. Walker, University of Kansas, Lawrence; Roy V. Wright, managing editor of *Railway Age*, New York; Edgar S. Nethercut, secretary of the Western Society of Engineers, Chicago, and O. P. Hood, U. S. Bureau of Mines, Washington.

Accidents at Coal Mines  
During May Resulted in  
Loss of 131 Miners' Lives

Accidents at coal mines in the United States during May, 1924, killed 131 men, according to information received from state mine inspectors by the Bureau of Mines. The production of coal during the month was 38,981,000 tons; thus the fatality rate was 3.36 per million tons. This compares with a rate of 6.44 in the preceding month, 3.40 for May, 1923, and an average rate of 3.68 for May during the ten years 1914 to 1923. For bituminous mines alone the fatality rate for May, 1924, was 3.04 per million tons, as compared 2.89 for May last year and a ten-year average rate of 3.25. For anthracite mines alone the rate was 4.65 per million tons, as against 6.18 for May, 1923, and a ten-year average rate of 5.84.

Accident records for the first five months of 1924 show 1,132 lives lost, representing a fatality rate of 4.81 per million tons of coal produced. For the same period last year the death rate was 3.94. The five-month fatality rate for bituminous mines alone was 4.73 in 1924 and 3.65 in 1923; for anthracite mines alone it was 5.21 in 1924 as compared with 5.53 in 1923.

Explosions of gas or coal-dust are the only class of accidents showing increased fatality rates in 1924 as compared with 1923. All the other main causes—falls of roof and coal, haulage, explosives and electricity—show reduced rates.

Accident-Prevention Work  
Spreads in Pennsylvania

Accident-prevention meetings conducted by the State Department of Mines in the anthracite districts of Pennsylvania have been so successful, Secretary of Mines Joseph J. Walsh said in a recent statement, that similar meetings will be conducted in the bituminous region. The bituminous inspectors have been instructed to take up the question of holding safety meetings with the operators. It is proposed that a series of meetings be held in every section of the bituminous territory.

"The gathering of the superintendents, mine foremen and firebosses in the various anthracite sections has had an excellent effect," Secretary Walsh said. "There was real co-operation and the men entered into the safety discussions with unusual interest.

"In the bituminous region, the stone dusting of mines to prevent explosions of coal dust is receiving a great deal of attention. The experiments conducted thus far have proved the effectiveness of this method of accident prevention and I expect that the operators generally will avail themselves of this means of lessening mine hazards. This method and others will be discussed at meetings in the bituminous region."

New River Co. Asks Rehearing  
Of Joint Mine Case

The New River Co., of West Virginia, has filed a petition with the U. S. Supreme Court asking a rehearing of the joint mine case which was decided by that tribunal June 9. The petition will not come before the court for action until October.

In the joint mine case, the Supreme Court, with Justice McKenna dissenting, upheld the constitutionality of rule 4 of the car service circulars of the Interstate Commerce Commission, in which the commission set down the policy that in periods of car shortage a mine located on more than one railroad should not receive a total allotment of cars in excess of its gross rating. This rule placed joint mines on the same basis as local mines.

In its petition for rehearing, the New River Co. asserts that, owing to the fact the case was advanced for argument, there was not sufficient time for adequate preparation on the part of the coal companies operating joint mines. Attention is called to the fact that rule 4 affects shippers of all goods who are served by more than one carrier if its application is carried to a logical conclusion. It is furthermore contended that the court paid more attention to the question of jurisdiction involved in this case than to the property rights which it is insisted were involved, or to the obligations of the carriers to provide adequate transportation. As another point the petition contends that under rule 4 joint mines are actually placed at a disadvantage in comparison with local mines.

Coal-Mine Fatalities During May, 1924, by Causes and States

(Compiled by Bureau of Mines and Published by Coal Age)

State	Underground											Shaft				Surface					Total by States						
	Falls of roof (coal, rock, etc.).	Falls of face or pillar coal.	Mine cars and locomotives.	Gas explosions and burning gas.	Coal-dust explosions (including gas and dust combined).	Explosives. ## Jones Preaches Safety By Using Rock Dust at Rocky Mountain Mines

John E. Jones, rock-dust expert, has spent a month traveling the highways and byways of the Rocky Mountain coal mining region preaching safety by dusting. His tour was arranged by the Bureau of Mines. Mr. Jones was borrowed by the Bureau from the Old Ben Coal Corporation, of Illinois. He had as traveling companions most of the time C. L. Duer, district supervisor of the Bureau's leasing division, and H. I. Smith, mining supervisor for the same division.

During late May, Jones, Smith and Duer spent several days at the Stag Canyon mines of the Phelps-Dodge Corporation, at Dawson, N. M., and on June 3, 4 and 5 they met R. L. Hair, division engineer, and Robert McAllister, mine inspector for the Colorado Fuel & Iron Co., and with them, visited the Morley, Sopris, Primero, Frederick, Berwind, Tabasco and Toller mines of that company. On the evening of June 4 Mr. Jones talked before the superintendents' and foremen's club of the Colorado Fuel & Iron Co. at Trinidad, Colo.

On June 5 the party visited the Bon Carbo mine of the American Smelting & Refining Co. and in the afternoon made a trip to the Lodge of the Whispering Pines near Stonewall, Colo. On June 6 and 7 Jones, Smith and Duer visited some of the Victor-American Fuel Co.'s and the National Fuel Co.'s mines. On the night of June 6 Mr. Jones spoke at a safety meeting in Walsenburg, Colo. Thus ran his "triumphal tour" so far as it covered the southern and central parts of the territory he visited.

Here We Have Jones and His Party at "Lodge of the Whispering Pines"

The party had visited the Bon Carbo coal mine of the American Smelting & Refining Co. that forenoon and were entertained at the Lodge. Those in the picture, left to right, are: C. L. Duer, district supervisor, leasing department, Bureau of Mines; Robert McAllister, mine inspector, C. F. & I. Co.; H. H. Bubb, general superintendent, American Smelting & Refining Co., Cokedale, Colo.; W. M. Laurie, deputy state coal mine inspector; Mr. Garrett, superintendent American Smelting & Refining Co., Bon Carbo, Colo.; R. L. Hair, division engineer, C. F. & I. Co.; H. I. Smith, mining supervisor, Bureau of Mines, leasing department; John E. Jones, safety engineer, Old Ben Coal Corporation, West Frankfort, Ill. The gentleman in the six-gallon hat must remain unknown. He probably was there merely to furnish atmosphere.

## Creating New Industries to Make Jobs for Miners

Indiana has sat around and done nothing for its jobless miners about as long as it can stand it. The state conservation department has a scheme and the first effort to try it out is being made now in and around Clinton. The department is making geologic and industrial surveys of the region to point out to capital the local resources which might be developed in order to create new industries in which the jobless and suffering union miners nearby can find work. The Clinton territory contains shales, sands, clays, gravels and ferruginous materials that might profitably be produced and used for the manufacture of concrete, road building and ceramic materials and other products. Dr. W. N. Logan, state geologist, is working on the matter.

## Merger Movement Appears in Pennsylvania

The Hillman Coal & Coke Co. of Pittsburgh, Pa., has acquired and merged with that corporation five other companies directly connected with the operating end of the coal industry. The merged company will operate under the name of the Hillman Coal & Coke Co. and will have a capitalization of \$8,752,000.

The companies taken in by the parent corporation are the Diamond Coal & Coke Co., the Merchants Coal Corporation, the Jenner Quemahoning Coal Co., the Pittsburgh & Baltimore Coal Co., and the Naomi Coal Co.

## Say C. & O. Imperils Rail Brotherhood Mine Road

The Brotherhood of Locomotive Engineers' investment in coal and rail properties in West Virginia, representing approximately \$3,000,000, faces ultimate failure if the Interstate Commerce Commission denies the application of the Coal River & Eastern Ry. for an order authorizing the company to operate in interstate commerce between coal mines owned by brotherhood members and the Chesapeake & Ohio R.R., according to representations to the commission by the Coal River & Eastern in support of its application.

The Chesapeake & Ohio is making a vigorous fight against approval of the application, contending that the lines controlled by the brotherhood members between their coal mines and the C. & O. are nothing more than spur tracks and therefore not admissible as a part of the interstate transportation system. The Chesapeake & Ohio also charges that the proposed capitalization of \$1,500,000 of the Coal River & Eastern is grossly excessive. It says the capitalization has as a basis \$750,000 as the value of surface right-of-way land worth but a few thousand dollars at most.

The tracks in issue connect the mines of the Coal River Collieries, a brotherhood company, in Boone County, W. Va., with the Chesapeake & Ohio. They are now owned and operated as a private railroad by the Coal River Collieries. The Coal River & Eastern was organized to take over the lines and operate as a common carrier in interstate commerce.

The Coal River & Eastern has authorized the issuance of \$500,000 of bonds and \$1,000,000 of common stock. It is proposed to deliver the bonds and \$250,000 of the stock to the Coal River Collieries for the railroad. The Brotherhood Investment Co., another engineer brotherhood organization, will offer \$750,000 of the stock to individual investors.

The charge is made by the Coal River & Eastern that the "real basis of the protest by the Chesapeake & Ohio is the pursuance of the policy which it has persisted in from the beginning of resisting the application of its group rates to independent short lines."

The Chesapeake & Ohio, however, says the Coal River & Eastern has admitted that the sole purpose of organizing the railroad company was to compel the Chesapeake & Ohio to extend its Kanawha district coal rate to the brotherhood mines and to compel the Chesapeake & Ohio to divide with the Coal River & Eastern its Kanawha district coal rate. It further says it refused to operate over the tracks in issue because they were unsafe for such operation.

Approval of the application, the C. & O. contends, would have the effect of transferring from the Collieries company to the C. & O. not only the expense of moving empty and loaded cars between the brotherhood mines and the connections with the C. & O. but also the burden of investment of the Collieries company in necessary railroad facilities connecting the C. & O. with the mines.

## Sop to Radicals of Northwest Seen in Democratic Anthracite Plank

Adoption Due to Pressure from New England—Non-Partisan Element Provides Loophole Against Hampering Private Enterprise—Selfish Interests Could Keep Regulatory Legislation Before Congress

By PAUL WOOTON  
Washington Correspondent of *Coal Age*

Pressure brought by New England members of the resolutions committee of the Democratic National Convention resulted in the adoption of this plank in the party's platform:

"We pledge the Democratic party to regulate by governmental agencies the anthracite coal industry and all other corporations controlling the necessities of life where public welfare has been subordinated to private interests."

While the loophole provided by the concluding phrase is large enough for a sound administration to make use of without being open to the charge of violating a platform pledge, this declaration paves the way for the radicals and the selfish to bring in and keep before Congress coal-regulation proposals.

New England has been more outspoken than any other section in regard to the desirability of keeping the government out of business and of preserving private initiative in business. Were the consumers of dry goods to propose regulation of the textile industry because there is an indefensible spread between the cost

of cotton and its manufactures New England would be ready to leave the Union. The sentiment in New England, which is typified by the Democratic plank, is not partisan. Republican members of Congress from those states have been active in forwarding the regulation idea in so far as anthracite is concerned. In this they have had the support of the radicals from the Northwest, who in addition to being radical also have had trouble in recent years in obtaining coal at prices which they regard as reasonable.

While the sessions of the Democratic resolutions committee, which framed the platform, were executive, it is understood that this plank provoked little comment. The committee was so torn by its differences over the Ku Klux Klan and the League of Nations planks that it had little time to give consideration to a "minor" matter such as regulating the coal industry.

There was no opportunity for the convention itself to pass upon the respective merits of the different planks. Separate votes were had only on the two controverted planks mentioned.

### More Connellsville Plants Return to 1917 Scale

Following the lead taken a few weeks ago by most of the other independent companies in the Connellsville (Pa.) coke region, W. J. Rainey, Inc., the Republic Iron & Steel Co. and the Crucible Fuel Co. reduced wages on July 1 to the Nov. 10, 1917, scale. As the Rainey company had been working full time up to the time of the reduction, some of the men decided they would not stand for the reduction, and did not go to work July 1. None of the men at the Royal and Allison plants went to work, so these plants were promptly closed down by the company for an indefinite period. At the Mt. Braddock plant about half of the men continued at work and this plant is continuing to operate. The Revere, Paul and Elm Grove plants continued operating in full.

The Republic Iron & Steel Co. has only two mines in operation in the region, Bowood and Martin, and these continued without interruption. The Crucible Fuel Co. plant, which had been idle for several weeks, resumed with a full force.

The only companies in the region now that have not gone back to the November, 1917, scale are the H. C. Frick Coke Co., subsidiary of the United States Steel Corporation, and the Monessen Coal & Coke Co., subsidiary of the Pittsburgh Steel Co. The Frick company has resumed operations at the Bridgeport mine and increased working time at the Colonial plants, but has closed Leisenring No. 3 mine.

### Ohio Miners Conciliatory on Wage Concessions

A two-day joint meeting of operators and miners in the southern Ohio field was held at Logan beginning July 1. The conference was called upon the invitation of miners in an effort to arrive at an agreement relative to concessions to be made on the wage scale in order to permit mines in that field to open in competition with other fields. Practically all of the larger operators were represented.

A conciliatory mood was shown by the miners as a rule and many propositions to reduce the cost of dead work and to reduce expenses generally were made. A joint scale committee was then named to canvass the situation and report back at a future meeting. Operators on the scale committee are James H. Pritchard, commissioner for the Southern Ohio Coal Exchange; F. S. Knox, Jr., New Pittsburgh Coal Co.; G. J. Jones, Ohio Collieries Co.; T. R. Biddle, Biddle Coal Co.; O. S. Newton, Sunday Creek Coal Co.; P. C. Morris, New York Coal Co.; R. T. West, N. D. Monsarrat, Monsarrat Bros., and H. Charleton.

### Last Kanawha Operators Retire from Union Fold And Announce New Scale

Despite persistent efforts of the owners of union mines in the Kanawha district of West Virginia to reach an amicable agreement with District No. 17, United Mine Workers, the last union operators in southern West Virginia left the fold Monday, July 7, according to an announcement by Duncan C. Kennedy, secretary of the Kanawha Operators' Association. Mr. Kennedy stated that every suggestion made by the producers was vetoed by the union's representatives, who frankly stated that it must be the Jacksonville agreement or nothing.

"To continue the 1923 wage scale in this district would mean to keep all the union men in it out of employment, as we could not operate the mines," said Mr. Kennedy. "The scale that we have offered is absolutely the best that we can do. The tonnage rates are the same as those in the 1917 scale, while the day wages are higher."

The new scale follows:

GAS SEAMS	
Pick mining.....	\$0.70½
Pick mining, Powellton Seam.....	.67½
Yardage in pick entries.....	1.24½
Machine loading in rooms.....	.44
Machine loading in entries.....	.49
Machine cutting in rooms and entries.....	.10
Machine cutting, turret and arewall.....	.06
NO. 5 SEAM	
Pick mining.....	.12½
Yardage and pick entries.....	1.37
Machine loading in rooms.....	.45
Machine loading in entries.....	.49½
Cutting rooms.....	.10½
Cutting entries and room necks.....	.11½
Machine cutting, turret and arewall.....	.06½
COALBURG SEAM	
Pick mining.....	.78
Yardage, pick entries.....	1.55
Machine loading, rooms.....	.50½
Machine loading, entries and room neck.....	.55
Machine cutting, rooms.....	.11
Machine cutting, entries and room neck.....	.12½
Machine cutting, turret and arewall.....	.07
RAYMOND CITY SEAM	
Pick mining over 1 in. screen per 100 bushels.....	\$4.16
Yardage in entries.....	1.55
Pick pillar coal, retreating, gas seam.....	.61½
Splint seam.....	.67½

No yardage to be paid in airways, following entries or breakthroughs, where the width exceeds 15 ft.

### GRADUATED SCALE FOR GAS AND SPLINT SEAMS

	Gas	Splint
Machine loading		
4 ft. and over.....	\$0.43	\$0.44
3 ft. 9 in. to 4 ft.....	.44½	.45½
3 ft. 6 in. to 3 ft. 9 in.....	.46½	.47½
3 ft. 3 in. to 3 ft. 6 in.....	.48½	.49½
3 ft. to 3 ft. 3 in.....	.50	.51

Machine cutting below 4 ft. shall be increased ½¢ per ton for each 3 in., in accordance with graduated scale. Graduated scale applies to all seams except those based on Coalburg.

### INSIDE DAY WAGE SCALE

	Hour Rate	Day Rate
Drivers, 1 mule.....	\$0.59½	\$4.76
Drivers, 2 mules.....	.61½	4.92
Tracklayers.....	.61	4.88
Tracklayers, helpers.....	.57	4.56
Slate shooters.....	.58	4.64
Greasers.....	.32	2.56
Trappers.....	.32	2.56
Spraggers and couplers.....	.33	2.80
Old men trappers.....	.43	3.44
Motor and machine runners.....	.62½	5.00
All other inside day labor.....	.56½	4.52

### July Circular Prices for Anthracite

	Broken	Egg	Stove	Nut	Pea	Buck No. 1	Rice	Barley
Philadelphia & Reading.....	\$8.95	\$8.95	\$9.10	\$8.95	\$6.00	\$3.00	\$2.25	\$1.50
Erie.....	8.70	8.70	8.80	8.60	5.50	3.00	2.00	1.50
Hudson Coal Co.....	8.80	8.80	8.80	Range	8.80	3.15	Boiler	1.60
Lehigh Valley.....	8.50	8.75	8.95	8.95	5.75	3.00	2.00	1.50
Lehigh & Wilkes-Barre Coal Co.....	8.00	8.55	8.55	8.55	5.75	3.00	2.00	1.50
Lackawanna.....	8.00	8.55	8.55	8.55	5.85	3.00	2.00	1.50
Lehigh Coal & Nav. Co.....	8.95	8.95	9.20	9.05	6.00	3.00	2.00	1.50

## Fierce Battle Now Rages Over Electric Cap Lamps At Oklahoma Coal Mines

They are still enjoying frontier stuff down in the coal fields of Oklahoma. Once they had the infamous "Molly Maguires." Now they have bolsheviki and "wop lawyers" and "saddle-colored coons" defying John L. Lewis' union and fighting "the battle of the cap lamps" with mass meetings where they threaten to kill somebody and into which hated but intrepid Bureau of Mines men walk unarmed. And all the while the three Hartshorn mines of the Rock Island Coal Mining Co. are tied up tight.

The whole business started almost two years ago, when the Rock Island company introduced electric cap lamps into its No. 12 mine. This move in the interest of safety was disapproved by a section of the district union organization and by State Inspector Edward F. Boyle. However, the company was sold on the idea, as were several other coal producers of the region. So in the settlement made for the Southwestern Interstate district in May, based on the Jacksonville agreement, the operators insisted upon an electric cap lamp provision, which was written into the contract after a long dispute.

In the dispute, Andrew McGarry, district president of the miners, and his district committee refused to accept an arbitration decision by Dave Frampton, an international union representative, in which Frampton recommended that the question go to the joint board for settlement under the contract while the lamps were used in Rock Island mines Nos. 7, 9 and 12 and while the mines went ahead and worked. But McGarry appealed to international union headquarters. By unanimous vote of the international board Frampton's decision was supported. Then the agreement was signed at Kansas City and everybody expected the Rock Island mines to go to work with electric cap lamps when the rest of the state resumed. But it was not so. State Inspector Boyle burst out with an order barring every sort of lamps underground in Oklahoma except carbide lamps.

Inspector Boyle's position is represented to be this: Electric cap lamps are so safe that mining companies using them will neglect their ventilation, to the detriment of Oklahoma miners. Boyle threatened to arrest the entire Rock Island railroad if necessary, and Mine Superintendent Jones in particular, if those cap lamps went below.

Then followed mass meetings of miners. They rallied around McGarry and around their paid lawyers and even around Inspector Boyle.

But it chanced that Frank Feehan, once president of District No. 5 miners' union, Irish by nature and with a fist the size of a ham at the end of each able arm, joined the Bureau of Mines service May 1 as a safety commissioner and was in Oklahoma at the time. Hearing about all this bloodthirstiness on the part of a controlling element of the Oklahoma district, believing in the righteousness of electric cap lamps and being Irish, he strode

©Underwood & Underwood  
**Richard F. Grant**  
President U. S. Chamber of Commerce

onto the platform at the next miners' outdoor mass meeting in Hartshorn, announcing that the assemblage could look him over. He was one of those hated government men they so yearned to puncture.

There ensued a dialog substantially as follows:

Mr. Feehan: "I'm going to address this meeting. I——"

Mr. Chairman: "You ain't neither. Nobody ast you to——"

Mr. Feehan: "I don't have to be asked. You have been misleading a lot of these miners and keeping them from working and——"

One hundred flivvers: "Whrrrt! Honk! Honk! Whrrrrrt! Whrrrt!"

Mr. Feehan: "Honk your horns off; I'm going to be heard. You men simply don't know what you're doing in this fool fight against electric lamps. I'm here to give you the facts in——"

A kindly voice: "Get ta hell outa here while you're still in one piece."

But finally Feehan said his say. And they do say it was full of straight-arm thrusts and jabs to the wind.

Before the meeting was over there was a different feeling evident toward Feehan and electric cap lamps. A few days later a delegation of miners called on Boyle and asked him to lift his ban on lamps. Their families are hungry and the Rock Island's three mines stand ready to give 900 of them almost steady work.

A wave of sentiment against the controlling union element in Hartshorn appeared to develop. For one thing a viciously worded "Warning" flier was posted all over Hartshorn against the "bolsheviki" and the "saddle-colored coons" and others thought to be responsible for the mine shutdown. For another, a miner met a union lawyer on the street and beat him up with what is known as neatness and dispatch.

But the latest news from the front in "the battle of the electric lamps" is that Inspector Boyle's order still stands and the three Rock Island mines are still down, although nearly 100 company men are daily going in and out of them wearing electric cap lamps without getting arrested.

## R. F. Grant Is New Head of U. S. Chamber of Commerce

Richard F. Grant, of Cleveland, vice-president of the M. A. Hanna Co. and a former president of the Cleveland Chamber of Commerce, was elected president of the Chamber of Commerce of the United States at a meeting of the board of directors, July 1 in Washington. He succeeds Julius H. Barnes, of Duluth, who declined another term. The board also elected Owen D. Young, chairman of the board of the General Electric Co., as a director to take the place of Lewis E. Pierson, chairman of the board of the Irving Bank-Columbia Trust Co., of New York, who was recently elected vice-president for the Eastern District of the National Chamber. John H. Fahey, Boston publisher, who was the second president of the National Chamber and who served several years as a member of the senior council, was elected an honorary vice-president.

In addition to his interests in the M. A. Hanna Co., one of the large producers of coal, iron and steel, Mr. Grant, the new president, has taken an active interest in public affairs. He was born at Owatonna, Minn., in 1879. He obtained his Ph. B. degree at Yale in 1899 and was graduated with a Bachelor of Law degree from the New York Law School in 1901. He took up the practice of law in Duluth in 1901 as a member of the firm of Sullivan & Grant. In 1909 he became general counsel of M. A. Hanna & Co., a partner in the firm in 1917, and in 1923, when its interests were taken over by the M. A. Hanna Co., he became vice-president.

Mr. Grant also is president of the Susquehanna Collieries Co., vice-president of the Hanna Furnace Co., president of the Virginia Ore Mining Co., and a director in the Cleveland Trust Co. and many other business institutions. He was appointed by President Wilson a member of the National War Finance Committee of the American Red Cross and served as chairman of the membership and finance drives for Ohio, Indiana and Kentucky in 1917. He also is a member of the American Bar Association and the American Iron and Steel Institute.

## Carnegie Plant at Clairton Is Now Biggest Coke Producer

With the first output of coke recently at the newly completed units of the byproduct coke ovens at the Carnegie Steel Co.'s works at Clairton, Pa., the plant became the largest in the world. It has a total of 1,134 ovens having an annual carbonizing capacity of 8,085,000 tons of coal and a yield of 6,350,000 tons of coke.

The latest addition, consisting of 366 ovens arranged in six batteries of 61 ovens each and having a carbonizing capacity of 8,500 tons of coal per day, had been under construction nearly two years. It will produce daily 6,000 tons of coke, 55,000,000 cu ft of gas, 90,000 gallons of tar, 215,000 lb. of ammonium sulphate and 25,000 gallons of benzol products.

## Practical Pointers For Electrical And Mechanical Men

### Reasons Why Open-Delta Connected Transformers Often Burn Up

Phase Relations Often Overlooked—Two Open-Delta Connected Transformers Cannot Carry Two-Thirds the Kilowatt Load of Three Fully Loaded Delta-Connected Units

By O. E. KENWORTHY

Electrical Engineer

Lehigh Valley Coal Co., Wilkes-Barre, Pa.

Though many operating companies have their transformers connected in open delta the principles under which the transformers operate, though quite simple, is not clearly understood and needs explaining.

To present this explanation let us consider Fig. 1 which represents schematically a three-phase load connected to the secondaries of three transformers. Both the load and transformers are connected in delta. Let us assume that the load is balanced and that each transformer is delivering the same amount of current.

Also let us represent the value of the transformer secondary currents by  $i$ ; then

$$i_1 = i_2 = i_3 = i$$

The line current we know has a value equal to 1.73 times the transformer secondary current. Representing the value of the line current by  $I$  we have

$$I_1 = I_2 = I_3 = I, \text{ and } I = \sqrt{3} \times i$$

The power delivered by each transformer can be indicated by the letter  $P$ . Hence

$$P_1 = P_2 = P_3 = P$$

Now if  $E$  is the voltage at the secondary terminals of each transformer.

Then  $P = Ei \cos \theta$  where  $\cos \theta$  is the power factor of the transformer secondary.

The total power  $P_t$  delivered by the three transformers is

$$P_t = 3 Ei \cos \theta$$

Substituting for  $i$  in this equation its value expressed in terms of line current we have when  $i = \frac{I}{1.73}$

$$P_t = 3 E \times \frac{I}{1.73} \cos \theta \\ = \sqrt{3} EI \cos \theta$$

Fig. 1—Usual Delta Connection

This illustration represents the current and voltage values when the load is balanced and three single-phase transformers are delta connected.

Fig. 2 shows the relation of the voltages and current. Fig. 3 is a schematic diagram of the load in Fig. 1 connected to the same bank of transformers but with one of the three transformers cut out of service, or in other words connected open-delta. Assuming that the load has not changed we will have the same values of line current as before, i.e.,

$$I_1 = I_2 = I_3 = I$$

However, the value of the transformer secondary current is now equal to the line current, but it lags behind the secondary voltage by an angle which is 30 deg. greater than before. Instead of the power factor of the secondaries being the cosine of  $\theta$  degrees it is now  $\cos \times (\theta + 30 \text{ deg.})$ .

The total power delivered by the two transformers is now

$$P_t = 2 EI \cos (\theta + 30 \text{ deg.})$$

For simplicity let us consider  $\theta = 0 \text{ deg.}$ ; then

$$P_t = 2 EI \cos 30 \text{ deg.} = 2 E \times \sqrt{3} i \times \cos 30 \text{ deg.}$$

By proportion we have.

$$\frac{P_t \text{ (1st case)}}{P_t \text{ (2nd case)}} = \frac{3 Ei \cos \theta}{2 \sqrt{3} Ei \cos (\theta + 30 \text{ deg.})}$$

but since  $\theta = 0 \text{ deg.}$

$$\frac{P_t \text{ first case}}{P_t \text{ (second case)}} = \frac{3}{2 \sqrt{3} \times 0.866} \\ = \frac{3}{3} = 1$$

which is true because we assumed the load to be the same in both cases. However, the following is also true: The power in one transformer in the second case was

$$E \sqrt{3} i \cos (\theta + 30 \text{ deg.})$$

and the power in one transformer in the first case was  $Ei \cos \theta$

Assuming again that  $\theta = 0 \text{ deg.}$

$$\frac{E \sqrt{3} i \times 0.866}{Ei} = 1.5$$

or each transformer in the second case is delivering 50 per cent more power than each transformer in the first case. The kilowatt capacity of each transformer is now exceeded by 50 per cent. Again, the kilovolt-ampere of each transformer in the second case is

$E \sqrt{3} i$ ; whereas in the first case it is  $Ei$ .

$$\text{Therefore } \frac{E \sqrt{3} i}{Ei} = \frac{1.73}{1}$$

or the kilovolt-ampere capacity of each transformer in the second case is exceeded 73 per cent. This fact is vitally important as will be recognized when it is recalled that transformers are rated on their kilovolt-ampere capacity. By inverting the last equation we get the decimal 0.577. We can say then that the kilovolt-ampere capacity in the first case is 57.7 per cent of the kilovolt-ampere capacity of each transformer in the second case.

Let us further consider a third condition using Fig. 3 again. We will now reduce the load to the point where the value of current in each transformer is equal to the current values in the first case, but at the same time keep it balanced. This means that now we have made the kilovolt-ampere capacity of each transformer in this, the third case, equal to the kilovolt-ampere capacity of each transformer in the first case. The line current is now

$$i_1 = i_2 = i_3 = i$$

The current in each leg of the three-phase load is  $\frac{i}{1.73}$ .

The load in the first case was

$$3 Ei \cos \theta$$

but is now  $3 Ei \cos \theta \div 1.73$

By proportion again

$$\frac{\text{load (third case)}}{\text{load (first case)}} = \frac{3 E \frac{i}{1.73} \cos \theta}{3 Ei \cos \theta} \\ = \frac{1.73}{3} = 0.577$$

Fig. 2—Vector Relations in Delta-Connected Circuits

Note that the line currents lag behind the corresponding transformer currents 30 deg. The line current is always the vector sum of currents in the two transformers.

Fig. 3—Open-Delta Current Relations

Here the line current is equal to the transformer current but it lags behind the transformer current 30 deg. more than when the three transformers are delta-connected.

This means that when two transformers are placed in open-delta service they are capable of delivering only 57.7 per cent of the kilowatt capacity that the three transformers delivered in the first case if they are to be kept within their kilovolt-ampere capacities. Going still farther, in the first case the kilowatt capacity of each transformer secondary was

$$Ei \cos \theta$$

whereas in the third case the kilowatt capacity is  $Ei \cos (\theta + 30 \text{ deg.})$ . Assuming  $\theta = 0 \text{ deg.}$

$$\frac{Kw_1}{Kw_3} = \frac{Ei}{Ei \times 0.866} = \frac{1}{0.866}$$

or the kilowatt capacity of each transformer in an open-delta bank is only 86.6 per cent of what it is in a closed-delta bank of transformers.

We can again prove the statement that two transformers working in open-delta can produce only 57.7 per

cent of the capacity of other transformers working in a closed-delta circuit by the following:

$kW_1 = \text{kw. of each transformer connected in a closed-delta}$

$kW_3 = \text{kw.} \times 0.866 = \text{kw. of each transformer connected in an open-delta}$

$3 \text{ } kW_3 = \text{total output of the transformers connected in a closed delta}$

$2 \text{ } kW_3 = 2 \text{ kw.} \times 0.866 = \text{total output of two transformers connected in a closed-delta.}$

$$\frac{2 \text{ } kW_3}{3 \text{ } kW_1} = \frac{2 \text{ } kW_1 \times 0.866}{3 \text{ } kW_1} = \frac{1.73}{3} = 0.577 \text{ or } 57.7 \text{ per cent.}$$

There are a few other facts in relation to the open-delta connection which are worth while mentioning at this time and they are as follows:

The voltages of the three phases on open-delta connections are a trifle unbalanced but for practical operation the lack of balance is really negligible.

In selecting transformers for a given load the open-delta connection requires transformers approximately 15 per cent larger than for the closed-delta, but there are two units instead of three.

In efficiency and weight the closed delta is practically the same as the open delta, but in cost the latter has a slight advantage.

## Selecting the Proper Size Wire For Electric Circuits

In inspecting the electrical equipment of almost any mine many of the feeder circuits will be found to be overloaded, the circuit being required to supply more motors than was originally intended when the feeder was installed.

Whenever a new motor is installed it is connected to the nearest supply line and no further consideration is given to the circuit. Within a short time the feeders are so greatly overloaded that the voltage drop is excessive and the wires become hot.

The safe current-carrying capacity of a single 1/0 rubber-covered wire is about 125 amp. Should this conductor be required to carry 200 amp. it would be overloaded 60 per cent. During the starting period of a motor such a conductor often would carry a much larger current and consequently become hot.

The safe current-carrying capacity of a wire is determined by the current which will pass through it continuously without causing it to become so hot as to damage the insulation or surrounding materials.

We all know that current flowing through a resistance develops heat. The same is true when a current flows through a conductor. The practice of carelessly overloading electrical conductors is more prevalent than generally believed, and the effects upon the conductors are quite serious. If the square of the current flowing through a conductor is multiplied by the circuit resistance, the heat developed, expressed in watts, may be determined. It will be noticed that the heat loss in the conductor varies directly as the square of the current, that is, if the current in any conductor is doubled, the heat is increased four times. Referring to the conductor hav-

ing a normal capacity of 125 amp. but carrying a current of 200 amp. we see that although the current has been increased only 60 per cent, the heat has increased 156 per cent.

This explains why burnouts occur when electrical equipment is overloaded. The excess load may not be very great, but the wires are greatly overheated.

To guard against overloading conductors, the current which is to flow in the line first should be determined, then a suitable conductor should be selected. Whenever the circuit is long, consideration should be given to the voltage drop, as it is possible to select a wire of ample current-carrying capacity but yet too small efficiently to deliver power to the motors connected at the end of the circuit.

The table shows the normal current-carrying capacity of each conductor which in no case should be exceeded, because the starting current required by most mine equipment is from one to four times the normal full-load current.

By following the suggestions given in the table, when installing new feeders, properly functioning circuits will be more common. In laying out new circuits due consideration should be given to future extensions.

### Area and Capacity of Rubber-Covered Wires

Wire Size	Area in Circ. Mil	Capacity in Amp.
14	4,133	12
12	6,555	23
10	10,430	32
8	16,466	39
6	26,304	43
4	41,827	65
3	52,740	76
2	66,407	90
1	83,770	107
1/10	105,738	127
2/0	133,426	150
3/0	167,884	177
4/0	211,876	210

## Gage Checks Wheel Center

The electric locomotive is one of the most important pieces of mining equipment yet it is in many cases more abused than any other piece of apparatus used in the mines.

Accidents caused by locomotives are nearly always attributable to incorrect operation or lack of proper care of the equipment. At best the service demanded from a mine locomotive is very severe. The strains and shocks that must be sustained even when starting an ordinary trip of mine cars are always quite great. When the track conditions are bad or many of the cars are loaded with rock the strains are much worse.

Consequently, if best results are to be obtained, the locomotive should always be kept in good repair. Dangers and damages to the locomotives, cars, track and workmen quickly multiply when the equipment is not properly designed.

One of the best ways to prevent delays and accidents is to repair the locomotives just as soon as conditions warrant. This, however, is not sufficient because a repair should be always as good as the original job.

Rolled-steel wheels are bored after being rolled and the possibility of the bore not being true, although remote, is quite possible. The bore of the wheel should be correctly centered.

Whenever a new locomotive wheel is used at the shops of the Pennsylvania Coal and Coke Corporation, Cresson, Pa., the device shown in the illustration is used to determine whether the bore is in the exact center of the wheel. The tool consists of a block having two parallel edges and an adjusting screw. This part of the device is placed inside the bore and the adjusting screw tightened to properly center it. When this is done the rotating arm, shown in the illustration, is exactly centered with respect to the axis of the hole. The adjustable arm is next extended and locked in a position where the short right-angled section just touches the outer edge of the wheel flange. By rotating this arm a check is made which determines whether the bore is properly centered.

The best way to avoid accidents is to provide accurately machined repair parts.

### Wheel-Testing Device

After the gage is put in position the adjustable rod is set to touch the outer edge of the wheel flange and rotated. If it touches the wheel at all points on the circumference the machinist is assured the wheel will not operate like an eccentric when mounted on a locomotive driving axle.

# Production And the Market

## Discouraging Conditions Fail to Dampen Optimism Of Bituminous-Coal Trade

Although visible foundation for hopefulness is lacking—in fact conditions seem to be growing even more discouraging for the time being—the bituminous-coal markets maintain a dogged confidence that the end of the prolonged period of depression is in sight or at the very worst is within hailing distance. As the coal business of late has fairly closely reflected general industrial conditions the predicted revival by leaders in the textile industry and the reported halt in the downward tendency in steel production are hailed as favorable omens. The president of one of the large coal roads, sailing for Europe last week, expressed his confidence that a turn for the better in business conditions would soon take place. All of which would indicate that the positive psychology that is the necessary prelude to a buying movement is being implanted.

### Hoover Reiterates Advice to Buy Now

The latest financial report of the Erie R.R. indicates the far-reaching effect of the curtailment of coal movement on the earnings of the coal-carrying roads. That the roads are not doing as much to help themselves as they might is indicated by the reiteration of Secretary Hoover's advice to buy coal before autumn.

Coal Age Index of spot prices of bituminous coal continues to move, if at all, within a narrow range, the figure for July 7 receding to 164, the corresponding price for which is \$1.99. The index figure on June 30 was 166, which represents a price of \$2.01 per net ton, a level which held for three weeks.

There has been a notable increase in activity at Hampton Roads, dumpings of coal for all accounts during the week ended July 5 totaling 401,935 net tons, representing a gain of 114,065 tons over the last week in June, when 287,870 net tons was handled. Coal dumped at Lake Erie ports during the week ended June 28, according to the Ore & Coal Exchange, was as follows: Cargo, 657,327 net tons; fuel, 41,393 tons.

The figures for the preceding week were 699,519 net tons of cargo coal and 41,168 tons of fuel coal.

The gradual upturn in the production of bituminous coal continues in evidence, output during the week ended June 28, according to the Geological Survey, reaching a total of 7,327,000 net tons, an advance of 125,000 tons over the revised figures for the preceding week, when 7,202,000 tons was produced. Anthracite production also registered an increase during the week ended June 28, when the output was 1,885,000 net tons. This compares with 1,823,000 tons during each of the two preceding weeks.

Quiet has settled over the anthracite market, demand being quite slow. As a result the supply is plentiful for practically all requirements, especially as interruptions to production by local labor troubles are less in evidence. Stove continues to lead in demand, the movement of egg and chestnut, such as it is, being largely dependent upon the amount of stove available. The smaller sizes, including pea and the steam, are inactive and accumulating steadily. The leading companies have added 10c. per ton to their July prices for egg, stove and chestnut, but the independents, having found it difficult to obtain even the old company circular, have announced no advances.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
June 14.....	10,573,000	7,152,000

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Screenings Softer

The week drilled along in the Midwest without much encouragement to the coal seller and producer. An anticipated slight strengthening of the market stirred up a slight increase in production, and then, when the market remained entirely dormant, prices had a tendency to weaken even from the low points of recent days. Thus southern Illinois screenings sank from a previous low of \$1.75 to a new low of \$1.60 and little moved at more than \$1.75 although there was a skim of country town business as high as \$1.90. Central Illinois prices were not affected. Indiana softened a shade, however.

And now the trade is looking forward to the latter half of this month to start the expected pick-up. Meantime strip mines in Illinois continue to get good running time meeting west Kentucky low prices. Anthracite throughout the Midwest made its scheduled increase of 10 or 12c. a ton without stirring up any business.

The Fourth of July lull prevailed during the week in southern Illinois and there was practically nothing doing, with several thousand cars of "no bills" of all sizes on hand. Much discontent prevails among miners on account of no work, although the field generally expects something to start after the Fourth. Some little activity in railroad coal

the last week has helped the situation somewhat. The mines are working from 1 to 2 and 3 days a week. Three days are rare and usually on railroad coal.

Things are quiet at St. Louis. A little domestic is moving for current business on account of wet cold weather. Wagonload steam has eased up and carload screenings shows a little activity, but other sizes are slow. Country steam is quiet and country domestic is just beginning to pick up. The tonnage of threshing coal this year is so small that it is not a factor any more. There is no change in retail prices and practically no early delivery of coal on account of rainy weather.

The oil refineries in the St. Louis switching limits are beginning to use more coal on account of warm weather making a better demand for gasoline. A continuous period of two warm weeks will show an increase of almost 25 per cent in the tonnage of coal used in the refineries.

### Kentucky Pick-Up Continues

While business is not at all rushing, volume has been somewhat better over the past week or ten days. Salesmen in the North and West are doing more, especially the commission salesmen, who have been making a hard drive, and retailers have been placing slightly better orders. Indus-

Index .....	164	166	166	197
Weighted average price .....	\$1.99	\$2.01	\$2.01	\$2.38

This diagram shows the relative, not the actual, prices on four-teen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

trial business continues a little quiet due to the dullness in some metal-working interests, the auto trade, etc.

The eastern Kentucky fields appear to be operating on a very fair basis and are increasing production as a result of better movement to the Lakes, to large retailers and to scattered utilities and industrial consumers. Cool weather has resulted in ice- and cold-storage plant consumption being relatively light, while refiners are principally burning fuel oil instead of coal on the present screenings market. Prices show no material change.

Western Kentucky is producing a little more. Prices in western Kentucky show no change over the week. Strip operators apparently are very busy. There has been a fair movement from western Kentucky on stove sizes to the South, with some scattered movement to nearby districts, Michigan and the North and Northwest.

### Northwest Trade Is Slow

The coal market at Duluth is still very quiet and sales are at a standstill with the exception of scattering public-utility contracts. The only movement of coal from the docks is by the railroad companies, which are taking coal for storage elsewhere against the time of the grain movement and possible coal movement.

The movement to the docks last week was good. Thirty-one cargoes arrived in all, of which three were hard coal. Twenty-two were reported en route, of which seven are hard coal. This report of the cargoes en route is exceptionally good for the present season. The docks here need about 1,400,000 tons of anthracite to carry through. This

means that the shipments must continue steadily until the fall in order to supply the demand.

The soft-coal situation may be worse than it looks too. Many mines are reported shut down and many of the lake carriers are tied up, as the result of a scarcity of cargoes in grain and ore.

Little anthracite is moving out now. Retailers report poor collections. Anthracite took its monthly increase of 10c. on July 1. Prices of bituminous are the same, and seem to be holding firmly.

July finds the coal market at Milwaukee exceedingly quiet but hopeful. With the exception of the usual monthly advance of 10c. on all grades of anthracite except buck-wheat, coal prices remain unchanged. Soft coal moves sluggishly. The record of cargo arrivals during June shows an aggregate of 143,197 tons of anthracite and 273,363 tons of soft coal. This makes the total receipts for the season thus far by lake 282,505 tons of anthracite and 599,462 tons of soft coal.

### West Fights for Business

A scramble for business in Oklahoma has resulted in a slash of from \$1 to \$1.50 a ton in the price of Henryetta coal. It is now quoted at \$4@\$4.50 for lump, \$3.50@\$4 for nut; \$3@\$3.75 for mine run and \$2@\$2.25 for screen-ings. Few mines are working.

There has been little change in the situation in Kansas. The threshing demand is a little more brisk, but there has been no improvement in the other markets. A slight increase in storage of Arkansas semi-anthracite is apparent. Prices on both Kansas and Arkansas coals are unchanged.

The only change noted in the Colorado market was another advance in prices effective July 1. Walsen and Canon City lump, nut and slack being \$4.75, \$4.25 and \$3.25 respectively. Crested Butte high-grade anthracite is \$7. Dealers still refuse to place summer orders and movements on all sizes are slow. Mines worked on an average of 18 hours last week. Forty-seven per cent of working time lost was attributed to "no market."

In Utah coal prices are on the upgrade. Operators have just announced a new schedule as follows: Lump, \$4.25; stove, \$4.25; domestic lump, \$4; nut, \$3.50; slack, \$1.50. This schedule is a little different from the old schedule in matter of grades. There has been very little storage of coal so far. Mines are operating a little better than two days a week. Practically no coal contracting is reported.

### Some Improvement at Cincinnati

The Cincinnati market shows signs of slight improvement. Both steam and domestic inquiries are numerous and real orders significantly better. There was more than a 15 per cent increase last week in moving tonnage from West Virginia and Kentucky in spite of a two-day rest in mining in connection with the national holiday. There also was a slight increase in lake business and buyers are saying here that their requirements for July will be from 30 to 50 per cent above those for June. The additional demand has not thus far caused any enhancement of wholesale prices, which continue so low as to afford the barest margin of profit.

With midsummer dullness prevailing in the domestic trade, there is practically no change in the Columbus market. Buying on the part of all classes of users is limited to immediate wants. Everyone seems to be playing a waiting game. Domestic trade is not quite as brisk as formerly. Householders in many cases are holding off in the belief that low prices will continue throughout the summer. Smokeless and splints are in the best demand from dealers although a fair amount of southern Ohio grades is sought. Retail prices are unchanged and are generally well maintained. Owing to lack of production and the closing of many large mines there is not much distress coal on the market. Steam trade is quiet, as has been the rule for several months.

Business in the Cleveland market fell off because of the holiday, but spot prices have not shown any weakening due to this cause. Demand for lake cargo fuel is lessening, which is attributed to the heavy tonnages now at the upper docks and the slow movement therefrom. Inquiries are negligible in the steam trade, and an active resumption of industrial operation is hardly looked for before the middle of July. Railroads report no improvement in the volume of general traffic and this has resulted in the curtailment of their consumption. Despite the conditions herein set forth, there is a feeling of optimism that the low point in coal

supply and demand has about passed, and an upturn will come within the next thirty days.

The Pittsburgh market shows no improvement. Prices are unchanged, except that slack is off 5c. This is due to offerings of strip mines, which crush coal to make slack, as that at least can be sold.

The entire trade at Buffalo is even more quiet than usual at this time of the year, though this is the dull season. And the outlook is far from promising. Prices are lower than at any other time since the war.

Inaction prevails in the Toronto market with practically no demand for soft coal. Although the hard-coal market is generally slow at this time of year, one Toronto firm reports fairly brisk business. The small dealers, however, are getting very few orders.

### New England Market Almost Stagnant

In New England the steam-coal trade drags along with almost no relieving features. Both all rail and by water there is still a great dearth of business, and in no direction is there much hopeful sentiment for July and August. Output is being held down in drastic fashion, but there are accumulations at practically every pier. Inquiry is extremely light and trade is almost stagnant.

At Hampton Roads the shippers are following out their close-hauled policy of May and June. On No. 1 Navy Standard Pocahontas and New River the range of \$4.25@ \$4.40 per gross ton f.o.b. vessel still obtains, with now and then a slight modification to dispose of distress coal. The less desirable grades sell down to \$3.85, but these are not much heard from in this market. Occasionally there are mixtures offering at the railroad wharves for distribution inland that account for prices on cars at less than \$5.50, but the No. 1 coals are being held with reasonable firmness at from that figure to \$5.75.

All-rail from central Pennsylvania trade is particularly dull, although not much different from any time since March. A few producers of non-union coals are making special efforts to move output this month to show the organization how idle it is to make labor contracts on the present union scale. Prices are therefore reduced in some quarters, but it is hard to find users even at a much lower level.

At retail the trade shows the demoralization consequent upon such a situation at wholesale. During last week a municipal school contract in the vicinity of Boston was taken at less than \$6.42 per net ton delivered. Subtracting teaming charges, marine freight, discharging, etc., leaves rather a small residuum for the operator.

### Seaboard Markets Dull but Hopeful

Conditions at New York underwent practically no change during the last week. Prospects of increased business are not evident at present. Coal continues to come to tidewater in increased tonnage, and as a result is being sold at what are considered low prices. Buying along the line is a trifle more brisk and prices are on a firmer basis. Few contracts are reported as closed recently. Some railroads are said to be adding to their reserves and contract coals are moving easily, but consumers are not inclined to take more than their contracts call for.

The Philadelphia market remains flat. The holiday may add a little impetus to the trade this week. Renewed buying is believed to be almost at hand, as stockpiles are disappearing, except at utility plants. Industrial conditions, however, are not much improved. There has been a slight softening in prices in desperate drive for business, and

this has induced a number of producers to meet quotations.

The situation in Baltimore and vicinity with regard to both steam and gas coal continues most uninterestingly dull. Low prices continue to prevail, but there is not much sacrificing at tide, as fuel handlers are cautious in placing their orders without an assured outlet. After a very poor start in June the export trade woke up and a fair total went out for foreign delivery. Fourteen steamers carried 59,450 tons of cargo and 4,720 tons in bunkers.

There has been no favorable turn in the Birmingham coal market. Inquiry is extremely weak for all grades of coal. Industrial requirements are lighter than for several years at this season. There is little call for spot domestic and retail yards have pretty well stocked upon contract fuel and are now waiting for the ultimate consumer to order his winter coal—a matter that seems to be receiving scant attention at this time, as the retail market is showing little activity. Quotations f.o.b. mines have changed very little for several weeks, a few grades being slightly lower.

### Hard-Coal Demand Quiet; Supply Ample

Labor troubles at the mines have ceased to affect the supply of hard coal at the New York tidewater market. Arrivals are ample for requirements. Except in the case of stove coal, demand is quiet; the movement of egg and chestnut in fact depends almost entirely upon the available tonnage of stove. All of the larger companies have added 10c. per ton to their June prices for egg, stove and chestnut, but because of the dullness of the market no change is reported by the independents, who find it difficult at times to obtain anything like company prices for their product. Some operators continue to break their broken coal in order to keep up mining, while pea coal is being stored in good volume. Steam coals are inactive and accumulating rapidly. There is practically no demand for free coals of the three small sizes and only contracts prevent heavier storing. Quotations for independent coals are low, only the best grades being held close to full company schedules.

The Philadelphia market is extremely quiet, the retail trade having slipped away to almost nothing and dealers are holding their orders generally. As expected, company shippers added 10c. a ton to the prices of the large sizes, leaving pea and steam sizes untouched. The independents also increased their prices on egg and stove, some leaving nut at last month's price, while others even reduced nut. Pea also was unchanged. Nut is moving so poorly that it may be necessary to store it soon, and pea is nearly as bad. Stove continues in strong demand, with egg also in good call. Retail prices are unchanged despite the increase at the mines.

Retail prices have again advanced in Baltimore as a result of new wholesale advances. The increase ranges from 25 to 50c. per ton, the new schedule being as follows: hard white ash, No. 1 (broken), \$15.50; No. 2 (egg), \$15.75; No. 3 (stove), \$16; No. 4 (chestnut), \$15.75; pea, \$11.50; buckwheat, \$8.50; Sunbury, No. 2 (egg), \$16; No. 3 (stove), \$16.25; Lykens Valley, No. 2 (egg), \$16.75; No. 3 (stove), \$17.

Foreign Market  
And Export News

British Market Better but Still Below  
Average; Output Rebounds

The Welsh coal market is slightly better since the Whitsuntide holidays and the return of the railway shopmen to work, but sales are still below the average and shipping tonnage is ample. The passing of the French political crisis and the slight improvement in the exchange has led to more business with France. Some of the older and more expensively operated pits have been closed down as the result of the increase in working costs brought about by the recent agreement between operators and miners. In some cases the Ministry of Mines has intervened to induce the owners to reopen the closed pits, which will be done if the miners agree to work double shift to reduce the costs of operation. South American business is below the average and European business is very slow.

There has been an increased number of contract inquiries on the Newcastle market, especially for gas coals, but otherwise the market remains in the

same state as last week. Prices are very low, in many cases below the cost of production. The French State Railways have placed orders for 10,000 tons of Durham coking coals of guaranteed analysis at 20s. f.o.b., and also for 30,000 tons of Welsh coals. The Swedish State Railways have taken 60,000 tons of steams at 26s. 9d.; Copenhagen Sugar Works, 15,000 tons of steam smalls at 12s. 5d. f.o.b.; West-eras Railway of Sweden, 20,000 tons of steams at 21s. f.o.b. The French Est Railway is negotiating for 20,000 tons of Durham coals, and the German State Railways are inviting offers for steam coals.

Production by British collieries during the week ended June 21, a cable to *Coal Age* states, was 5,173,000 tons. This was a marked rebound from the previous week, when the output was only 3,236,000 tons owing to the observance of Whitweek, according to the official Board of Trade returns.

**Fair Trade at Hampton Roads; Outlook Is Promising**

Business is fair at Hampton Roads, with some contracts going to New England and with foreign movement dropping slightly, due to expiring contracts. General bunker business also is fair, though the market has weakened slightly.

There has been the usual slow-up for the holiday and shippers predicted a pick-up for the following week, the reduced holiday supply being expected to have a tendency to cause the market to strengthen somewhat.

The tone of the market is dull, but the outlook is promising, although no unusually heavy business is in sight for the immediate future. June's dumping record showed an improvement over the previous month, and the trade appeared fairly well satisfied with the situation.

**Conditions in French Market Show Slight Change**

The situation in the French coal market shows comparatively little change. Output is increasing and is being pushed as much as possible. Demand, however, is equal to supply; in fact, in the Nord and Pas-de-Calais there are no available stocks, the volume of orders in sized products precluding the collieries disposing of any quantities other than those covered by contract. The bituminous grades are quite neglected.

The recent decline of sterling has lessened the difference prevailing between the prices of British and French coals; nevertheless, the quotations on the latter continue to be the more attractive. The prices of anthracites remain prohibitive.

The supply of rolling stock to the mines is satisfactory and the freight

rate is quoted at 20 fr. Bethune-Paris. In the Nord and Pas-de-Calais, the complements of wages granted by the companies as from November, 1923, and continued until June 30 of this year, have been renewed until Sept. 30, at which date further steps will be taken. It is likely, therefore, that prices will remain unchanged. However, until July 31 or Aug. 15, a summer premium of 8 fr. per ton will be allowed to retailers.

**Ruhr Prices Cut 20 per Cent**

Price schedules on all Ruhr district coals have been reduced 20 per cent, in order to stimulate sales, which have recently taken a sharp decline.

## News Items From Field and Trade

### ALABAMA

The Sloss-Sheffield Steel & Iron Co. has entered the retail coal trade by the establishment at its City Furnace plant of a battery of storage bins from which it will dispense direct to consumers its lump and washed nut coal as well as its line of domestic nut coke.

It is reported from Scottsboro, Jackson County, that the Pierce coal mines, near Limrock, have been purchased by a corporation which will place the mines in operation soon. This operation has been idle for about ten years. A spur track is now under construction from Limrock, on the Southern Ry., to the mine site.

The board of mine examiners will hold a session in the offices of C. H. Nesbitt, chief mine inspector, Lincoln Life Bldg., Birmingham, July 21-24, to consider applications from candidates who would occupy positions as mine foremen and firebosses in Alabama mines. The personnel of the recently appointed board is as follows: C. H. Nesbitt, chairman; Sam Y. Leith, C. M. Parker, C. E. Bowron, F. G. Long and J. S. Kellum.

### COLORADO

During the month of May, Colorado mines produced 678,345 tons of coal. This is a decrease of 54,128 tons as compared with the corresponding month last year. The total number employed in and about the mines in May was 12,648.

The Victor-American Coal Co. has abandoned its Grey Creek mine and the State Public Utilities Commission has granted the Colorado & Southern R.R. permission to tear up the 7-mile spur line from Beshoar Junction to the mine site.

### IDAHO

Teton coal is to get railroad service. The State Utilities Commission, following the long series of recent hearings, has ordered the Oregon Short Line to repair and operate its 11-mile spur from Tetonia Junction to the Brown Bear mine of the Teton Coal Co., and the coal company is required to post a bond of \$27,160 with the railroad company, covering the cost of putting the line back into service. The coal company guarantees to ship at least 29,920 tons of coal per year. The railroad had objected to spending the money on the spur, asserting that the effort of H. F. Samuels to open the mine was mainly a political move to further his probable candidacy for Governor and that he did not intend to produce much coal.

Samuels insisted he was in earnest as a coal producer and got a good many towns worked up over the prospect of getting coal from him at low cost. The hearings attracted much attention.

### ILLINOIS

A. T. Allen has been appointed coal transportation agent of the Chicago & Eastern Illinois Ry. at Chicago. The position of manager of coal traffic, formerly held by the late D. R. Patterson is abolished. Mr. Allen's appointment was effective July 1.

Some Illinois mines are reopening. The Marion County Coal Co. has resumed work at its Glenridge mine after having been closed down since April 24. The mine at Rutland, which has been at a standstill for several weeks, also has been reopened. Coal rights under adjacent property have been obtained and it is thought that these rights will pave the way for other additions.

A receiver was asked for the O. K. Coal Co., of Marissa, in a petition filed in U. S. District Court at East St. Louis, on June 27, by Arthur C. Smith and John Henderson, stockholders, both of St. Louis, Mo. Gross mismanagement is charged. The company was incorporated in 1917 and operated under its own name until 1922, the petition states, at which time it entered into an agreement with the Egyptian Coal & Mining Co. whereby the latter gained control of the O. K. company, both companies having the same majority stockholders and officers. It is further alleged that the mines of the company were closed down this year and have been allowed to fill with water and gas, so that they are unworkable. The property of the O. K. company is estimated at \$125,000 in the petition.

### INDIANA

Cairy Littlejohn, of Indianapolis, state mine inspector and formerly a resident of Hymera, Ind., has been admitted to the Sullivan County Bar.

About 60 per cent of Indiana mines are idle and the coal mining industry in the state still remains in the dumps. If the present rate of production is maintained during the remainder of the year, only about 50 per cent of the normal production will result. Operators say Indiana coal is suffering because of competition from non-union fields. They say a lower wage scale would be the solution.

W. J. O'Brien, of Chicago, is suing to gain possession of a majority of the

stock of the Glendora Coal Co., which he claims to have bought and paid for with \$577,500, but which has never been completely delivered. His suit is against the First National Bank of Vincennes; Joseph E. Paplante, its president; the Glendora Coal Co. and John L. Baker, its president, and Frank P. Emison, its treasurer. O'Brien claims Baker deposited only 1,785 shares of the stock and not the full 2,100, which would have given O'Brien control of the company.

According to a report by Cairy Littlejohn, chief mine inspector of Indiana, 12,289,296 tons of coal was mined in the state during the first half of the present fiscal year. The report shows that \$20,932,231.52 in wages was paid to Indiana miners during the same period. The total amount of wages for all the last fiscal year was \$45,920,877.54. The number of employees for the first six months of the present year, as shown in the report, totals 23,861, as compared with 31,189 for all of last year. The number of fatal accidents totals 33, which is less than for the same period of last year.

### KENTUCKY

W. H. Jones, of Prestonsburg, has been appointed by Governor Fields as Chief Mine Inspector of the state, succeeding L. V. Blenkinsopp, of Lexington, whose term of office has expired, the latter having been appointed when Gov. Morrow, Republican, was in the Governor's chair.

Fred M. Sackett, of the Byrne & Speed Coal Co. and allied interests in Louisville, which operate a number of coal mines in the state, has filed papers as candidate for Republican nomination for the U. S. Senate, and will wage an active campaign in the autumn for election if he is nominated.

The annual production report of mines in the northeast Kentucky district recently completed by C. J. Neekamp, secretary of the Northeast Kentucky Coal Association, and F. E. Durham, statistician, shows the tonnage produced from 1910 to 1923, inclusive. A black and white chart in thermometer form shows production from 1906 to 1922, inclusive, along with tonnage for each mine, and total tonnages by mines from 1910 to 1922, inclusive. Figures by mines for 1906 to 1909 are not available, and only totals for the field in those years are shown. In 1923 the field broke all previous records with a total production from 180 mines of 7,464,185 tons, bringing field production from 1906 through 1923 to 55,672,525 tons.

The Himyar Mines, of the Himyar Coal Co., Domino, in Perry County, have closed indefinitely. A fire underground started several weeks ago. The blaze followed an explosion in which one man was killed and others hurt. The mines were sealed and the fire was reported out. When the fans were again started the blaze rekindled, and the mines have now suspended indefinitely.

Increases in tax assessments are being fought by many coal companies in the state. The St. Bernard company, whose properties were assessed at \$1,534,000, is fighting an increase of \$800,000; the Fordson Coal Co. is fighting an increase from \$2,000,000 to \$3,000,000, and the Kentland Coal Co., in Pike County, which made a return of \$1,600,000, is protesting a \$400,000 increase.

The Louisville & Nashville R.R. Co. some weeks ago denied a report of friction existing between that road and the Southern Ry. whereby the Southern would withdraw from the Middlesboro field, over refusal to pay an increased rental use on trackage of the L. & N., yet for some reason mines serving the Southern are shutting down. The Fork Ridge mines, employing 300 men, were ordered down on July 1.

Loading records from western Kentucky show four mines of the St. Bernard Mining Co. producing coal on June 26 and 27 under the new agreement with 20-per cent reduction in wages, whereby the workers withdrew from the United Mine Workers, and formed a Mutual Welfare Association. It was reported on June 28 that 310 men had been busy getting some of the plants in shape for operation, and that of the men who returned to work on June 25, six quit the next day.

## MINNESOTA

Robert D. Loudon, president of the Loudon Coal Mining Co., of southern Illinois, now in receivership, has been indicted in Minneapolis by the grand jury, on a charge of embezzlement. He was arraigned in district court and entered a plea of not guilty. Bail was fixed at \$5,000. The charge brought by the grand jury was for grand larceny in the first degree, and alleges that as president of the company, he

embezzled \$2,600 of company funds by trading 2,600 dollar bonds for 160 acres of Montana land, placed in his own name. The Loudon Coal Co. was formed in Minneapolis by Mr. Loudon to operate coal yards to association members and thereby reduce the cost of fuel.

## NEW YORK

The Pennsylvania Coal & Coke Co. reports a May deficit of \$49,540 after ordinary taxes, depreciation and depletion, but before federal taxes, comparing with a profit of \$79,707 a year ago. For the five months the deficit was \$86,513, against a profit of \$549,320 in the same period of 1923. The gross revenue in May was \$430,046, representing a decline of \$306,580 from last May.

The United States Distributing Corporation, New York City, will handle in excess of 5,000,000 tons of anthracite and 2,000,000 tons of bituminous coal in 1924, according to a statement by Harry N. Taylor, president of the corporation. This compares with 1,000,000 tons of anthracite and 300,000 tons of bituminous coal distributed last year. Both the corporation's full sales department and its distributing subsidiary, the U. S. Trucking Corporation, have extended their facilities this year to make possible the placing of this additional tonnage.

Since the beginning of Burns Bros., fiscal year, April 1, the company has retired \$94,300 of prior preference stock at 120 and dividends, leaving only \$775,000 of the original \$1,292,100 outstanding, Frank L. Burns, president, announced last week. Owing to the cool weather the earnings in April and May were better than were anticipated, and the company will enter the fall better off than last year, he declared.

## NORTH DAKOTA

At the annual meeting of stockholders of the Washburn Lignite Coal Co., held at Minneapolis, plans were laid for continuing the successful operation of its mines at Wilton, where the company has produced lignite since 1901.

The following officers were re-elected for the ensuing year: President, W.

P. Macomber, Wilton, N. D.; Vice President, Stanley Washburn, Lakewood, N. J.; Secretary and Treasurer, Jefferson Steiner, Bismarck, N. D.; General Manager, W. P. Macomber, Wilton, N. D.

## OHIO

The Jobs mine, at Murray City, has resumed work after a long suspension. About 50 men have been given work.

William S. Harman, of the W. S. Harman Coal Co., of Columbus, will soon start the development of a large stripping operation adjacent to the new power plant of the Ohio Power Co., located at Philo, on the Muskingum River. Mr. Harman and associates acquired the tract some time ago and a contract to furnish fuel to the power company has been signed and thus active development work will start. Steam shovels and other stripping equipment will be installed.

Bondholders of the Superior Coal & Dock Co., of Superior, Wis., which is a subsidiary of the Maynard Coal Co., of Columbus, now in the hands of William S. Harman and Frank L. Stein as receivers, met with representatives of the Ford Motor Co. in Columbus July 1 to discuss the offer made by the Ford Co. of \$658,500 for the dock properties. No change was made in the offer and a number of legal tangles appeared to cloud the situation. Further conferences will be held which may result in closing the deal.

A new chapter of the Joseph A. Holmes Safety Association has been organized at Senecaville, Ohio, designated as Chapter No. 95. The officers of this chapter are: J. S. Channel, president; C. O. Harding, vice-president; M. C. Miley, secretary-treasurer, and W. Christian, educational director. A charter was granted Cambridge Safety Chapter No. 96, Cambridge, on May 29. The officers of this chapter are: John Rigby, president; Charles Richardson, vice-president; H. C. Knapper, secretary-treasurer; J. W. Rarick, safety director, and Arthur G. Faught, educational director.

Medals have been received at the headquarters of the Ohio Mining Department, Columbus, from the Wheeling Steel Corporation, Wheeling, in recognition of the good work done by the chief and assistant inspectors of the department in the explosion of the Benwood mine in April in which 119 lives were lost. The medals are of bronze bearing a wreath inclosing a miner's safety lamp and the inscription "For Exceptional Service Rendered Humanity." On the reverse side is the inscription "Benwood Mine Explosion, April 28, 1924." The medals were awarded to Jerome Watson, chief inspector; P. W. Moore, first-aid and rescue supervisor, and the 10 Ohio deputies who aided in the rescue work.

The Red Jacket Consolidated Coal & Coke Co., which formerly had general offices at Detroit, has been taken over by the W. M. Ritter Lumber Co., of Columbus, and the general offices moved to the Hartman Building, Columbus. The company, which controls a large acreage with a capacity of ap-

Courtesy U. S. Distributing Corp.

## Underwood Colliery, Pennsylvania Coal Co., Throop, Pa.

This mine on the Erie R.R., near Pittston, Lackawanna County, Pennsylvania, mines coal from six seams. The many beds in the anthracite region make its operations more permanent than those in the bituminous field.

proximately 100,000 tons monthly, is functioning as a separate entity, although a subsidiary of the Ritter company. H. T. Wilson is president and T. H. Wilson is sales manager. The properties are located in Mingo County, West Virginia.

### OKLAHOMA

Drilling and shoveling contests among miners of the Miami district, with prizes ranging from \$10 to \$100, are to be held in July, during the Imaim Amohalko fiesta, under rules similar to those which prevailed last year.

Tough times in coal did not discourage the King Koal Karnival, which is held annually at Henryetta. This year it ran from July 1 to July 5, drawing people from many surrounding towns to see the street pageant and to enjoy the street carnival of the type that has been conducted in Henryetta each year for four years. Coal displays in store windows and special coal advertising of all sorts during the week helps merchandise the coal produced in the Henryetta field.

### PENNSYLVANIA

The Westmoreland Coal Co. is preparing to develop a large tract of Pittsburgh coal recently purchased in Sewickley township, Westmoreland County.

Because mine workers at the Woodward colliery of the Glen Alden Coal Co., at Edwardsville, Luzerne County, closed down the operation to hold election of officers, district officials of the United Mine Workers may refuse to recognize the elected officers. Several fights occurred at the colliery during the day of election and arrests were made. An insurgent faction carried the election.

The Hazle Brook Coal Co. now has another colliery on its chain of operations. The new operation is located at Good Springs, near Maryd. The Skidmore and Buck Mountain veins have already been reached and fuel is being shipped.

A 5-ft. vein of coal was reported to have been struck last week in the No. 4 slope of the Evans Colliery Co. at Beaver Meadow, where Contractor Peter Ecker, of that place, is driving a tunnel from the Buck Mountain to the lower Gamma vein.

The Alliance Coal Co., a subsidiary of the Lehigh Coal & Navigation Co., is planning to install automatic controls on its pumps, as it has already done with its fans. These vital machines will be handled by one man, who will control them by means of a gage located in a substation on the surface.

That advertising urging the installation of special grates for the burning of small sizes of anthracite coal brought results is evidenced by the reports of dealers in the anthracite region. In Freeland, Pa., in the heart of the hard coal region, agencies report a large sale of special grates. The Coxie Traveling Grate Company at Port Carbon is now working on a new small heating plant which will burn steam sizes of anthracite.

The Shamokin Colliery Co., a \$250,000 corporation of Boston and Wilkes-Barre capitalists, recently acquired from Daniel H. McGhee and Joseph J. Evans, of Shamokin, their colliery located about two miles west of Mt. Carmel. Matt Stevens, of Wilkes-Barre, is president and general manager of the new company, and Ernest P. Chapin is secretary and treasurer. The Shamokin company recently leased a section of coal land and some valuable culm banks just west of the new acquisition.

The Rochester & Pittsburgh Coal & Iron Co. is rebuilding the tippie of its Helvetia mine near Punxsutawney, which was burned last October, employing Heyl & Patterson of Pittsburgh to do the work. The cost is to be about \$50,000 and the tippie will be finished in two months, when the mine will start up.

### UTAH

Thirty-five prominent Salt Lake City business men met at the Alta Club one day recently where they gave a dinner in honor of L. F. Rains, head of the Carbon Fuel Co. The dinner was in recognition of Mr. Rain's part in developing the steel industry in Utah.

The U. S. Land Office will in the near future contest 20,000 acres of coal land in Emery and Carbon counties, claimed by the state as school sections. The national government contends the mineral character of the land was known prior to the date the state rights attached.

A coal tract comprising 1,818 acres in the Castlegate district has been let by the Register of the Land Office to L. A. Lawyer. It is one of the largest single units to be let in recent years. Under the terms of the lease not less than \$50,000 must be spent on bringing the property to an annual production of 60,000 tons of coal in three years. The government royalty is 10c. a ton.

### VIRGINIA

The Amherst Coal Co. and the Logan County Coal Corporation have consolidated, and the name of the latter will be used for the new firm. The Norfolk office will be in charge of H. M. Fadley, former manager for the Amherst Coal Co.

### WEST VIRGINIA

It having been established that the fire which resulted from the gas and dust explosions in the Benwood mine of the Wheeling Steel Corporation on April 28 has completely died out, the State Mine Department has recalled its corps of inspectors in charge since the explosion and the company is now preparing to resume operations in the mine. Men are at work clearing the motor road and placing new timbers along the main entry, which will require several months and will involve the expenditure of a large sum of money. An order has been promulgated to the effect that none but electric safety lamps shall be used by the employees at all mines of the corporation.

It is stated that ventilation at the Benwood mine at the present time is better than in any other mine in the northern Panhandle. Brattices and walls built on the aircourses and other changes made under state supervision insure a constant flow of air into all of the workings.

### WISCONSIN

Bertram M. Ainsworth, of Milwaukee, who skipped when his arrest was ordered for conspiracy and using the mails to defraud in the Valley Coal & Dock Co. bankruptcy case, was captured by the police in New York City, June 25, and has been returned to Milwaukee for trial. Ralph Clements, of Cleveland, the other operator of the Valley company, surrendered some time ago and is out on bail awaiting trial.

### CANADA

T. H. Williams has been appointed manager of the Reserve Mine, Western Fuel Corporation of Canada, to succeed Robert Henderson, resigned.

The Toronto Board of Health has let the contract for the anthracite required for the building under its control to W. Scott & Co. at \$15.50 per ton. There were six tenders for the contract, all of which quoted the same figure.

On June 20, the first box of coal was raised from No. 1 B, the newest and best equipped colliery of the Dominion Coal Co. at Glace Bay, N. S., which has cost nearly \$3,000,000. It has a normal capacity of about one million tons yearly. No. 1 B is exclusively an undersea mine, but how far under the Atlantic it will be possible to continue the extraction of coal will depend on how far ventilation can be economically developed.

The Canadian Collieries (D), Ltd., is opening a new slope in the Bright district, Vancouver Island, on the outcrop of the Wellington seam. It will be operated as an extension of the Wellington Ladysmith Colliery. The same company is unwatering No. 8 shaft, Cumberland. This development was carried out in the year 1914 and was stopped to permit concentration of production from other workings.

At the annual meeting of the Nova Scotia Mining Society at New Glasgow, N. S., on June 24, President Alex. McNeil, general superintendent of collieries for the British Empire Steel Corporation, in his presidential address emphasized the necessity for an increased duty on coal. He contended that if Nova Scotia was to compete with American coal in the markets of Quebec and Ontario the cost of production must be lowered and freight rates decreased.

### New Companies

The Standard Fourth Vein Coal Co., of Linton, Ind., has been capitalized with 5,000 shares of no par value stock to mine, sell and ship coal and coke and other minerals. The incorporators are G. B. Taylor, of Erie, Pa., C. F. Shepard, of Ladd, Ill., and Peal Poole, of Linton, Ind.

## Traffic News

### Rate Cuts Allowed, Advances Denied in Kansas

The Kansas Public Utilities Commission has issued an order reducing freight rates on coal from southeastern Kansas to points in the central and western parts of the state. Some time ago the railroads filed an application for authority to increase some rates and lower others on joint line hauls of coal from the Kansas field. About 200 towns were affected. The commission denied the application to increase the rates, but allowed the railroads to make the reductions they proposed. The reductions amount to from 10c. to 25c. a ton. The Santa Fe, Katy, Rock Island, Union Pacific and the Frisco are the railroads involved.

### North Dakota Not to Call Parley On Lignite Rates

The North Dakota State Railroad Commission will not call any conference for the purpose of considering new lignite rate tariffs, Frank Milhollan, chairman of the commission, said last week after an announcement had been made that the South Dakota commission was considering such action. The North Dakota commission which recently dismissed the complaint of railroads for higher lignite tariffs, takes the position that as the proposals for increased rates were instituted by the carriers, the burden of proof naturally fell upon them and if there is to be any conference of interested parties it would be up to them to take the initiative, Mr. Milhollan said.

### B. & O. Must Pay Damages In Coke Rate Case

The Interstate Commerce Commission in a formal report in the case of the Pittsburgh Steel Co., against the Baltimore & Ohio R.R. and connecting lines held that the rate on coke, in carloads, from Cascade, W. Va., to Monessen, Pa., between June 10 and June 20, 1923, were unreasonable. The complainants were awarded \$7,789 with interest as reparation damages.

### Decision on C. C. & O. Lease May Be Deferred

Decision of the Atlantic Coast Line and the Louisville & Nashville as to whether or not they will accept the Carolina, Clinchfield & Ohio lease under the terms laid down by the Interstate Commerce Commission may not be definitely decided for several months, according to a report last week. Since the order was handed down by the Interstate Commerce Commission thirty days ago, counsel for the railroads concerned have been making a careful study of the situation, but have not made a report. Under the terms of the order of the Interstate Commerce Commission the Atlantic Coast Line and the Louisville & Nashville will have six months in which to make their decision.

### Assigned Car Case Deferred Again

The Interstate Commerce Commission announced on July 5 the tenth postponement of the hearing on distribution among coal mines of privately owned cars and cars for railroad fuel until Nov. 1, 1924. A hearing had been set on the last postponement for August 1.

### Indiana Rate Cuts Hold

An injunction which nineteen railroad companies operating in Indiana sought in a suit filed in March to prevent the Indiana Public Service Commission from enforcing a schedule of rates which the commission approved in February on coal shipments from producing points to different group destinations, all in Indiana, has been denied by Judge Hay, in Superior Court, in Indianapolis. The court said there was no evidence to show the proposed rates would not be sufficient to produce an adequate return, including a reasonable profit, or that the rate would force the reduction of any rate, either interstate or intrastate, below such a level. The railroad companies, in their suit, alleged the schedule of rates was too low to yield a fair return.

Petitions asking lower freight rates on coal from certain Indiana points have been filed with the Interstate Commerce Commission against the Chesapeake & Ohio and other railroads. Rates on coal from Ohio, West Virginia and Kentucky to Elkhart, Ind., have been lowered, the petition states, and adjustment of eastern rates is asked.

## Obituary

Maynard O. Gibbs, mining engineer and former well-known resident of Bluefield, W. Va., was killed a few days ago by a fall of slate in the No. 10 mine of the United States Coal & Coke Co. at Gary. The room in which Mr. Gibbs was killed had been regarded as dangerous for some time and Mr. Gibbs was warned as to its condition before he entered it. During the world war Mr. Gibbs served overseas. Returning to the United States in 1919, he obtained a position with the United States Coal & Coke Co. at Gary as a mining engineer. Mr. Gibbs was graduated from the Virginia Polytechnic Institute, at Blacksburg, as a civil and mining engineer. He was about thirty-two years of age and is survived by his wife and one daughter, aged six years.

## Coming Meetings

**First International Management Congress**, Prague, Czechoslovakia, July 21-24.  
**Rocky Mountain Coal Mining Institute**, Summer meeting, Aug. 7-9, Rock Springs, Wyo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

**New York State Coal Merchants Association, Inc.**, 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

**National Safety Council**, Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

## New Equipment

### Power-Factor Correcting Unit

A static condenser of an improved design, said to be durable, efficient, of light weight and low cost per kilovolt-ampere, is now on the market. This device is designed to enable industrial concerns to improve the power factor of their electric circuits and thus increase the available capacity of their generators and transformers, decrease the energy losses in their distribution systems and improve their voltage regulation.

A specially high-quality dielectric is used by the manufacturers of this device, enabling them to cut down the thickness of the layers without reducing their efficiency, thus reducing the size and weight of the condenser.

Among other advantages claimed by the General Electric Co., who markets this condenser, are efficiency, simplicity of operation and convenience of location. No attendant is required, the condenser being placed in operation by closing a control switch. It may be left on the line indefinitely with but occasional inspection. Operation is claimed to be practically noiseless. The condensers may be designed for out-of-door service. There are no moving parts, thus eliminating the need for a special foundation.

Low losses are also a feature of this device, the losses in 2,300-volt equipment being approximately one-half of one per cent of the rated kilovolt-ampere capacity. For low-voltage equip-

Static Condenser Unit

This is a three-phase, 60-cycle, 180-kva. 2,300-volt static condenser. Power-factor correcting equipment will increase the kilowatt capacity of transformers, lines, and switches. Power savings are also possible because of the lower heat losses.

ments, a transformer is included, the losses being approximately 3 per cent.

The improved condenser consists of a number of units, a reactance for dampening out the higher harmonics in the voltage wave, a discharge resistance for draining the condenser charge when disconnected from the line and an oil circuit breaker for the control of the equipment. The number of condenser units is directly proportional to the capacity required. Each unit is composed of a large number of couples of metal-foil paper laminations as a dielectric. These units are mounted on a rack.

The condensers are being marketed for 40- to 125-cycle circuits, of 220 to 2,300 volts, in six sizes from 30 to 300 kva. For larger capacities, the complete units are arranged in tiers or banks. The weights of the standard units, without reactor and transformer, range from 805 lb. for the 30-kva. size to 5,510 lb. for the 300-kva. size.

### Cable Connector with Enclosed Fuse

The Ohio Brass Company of Mansfield, Ohio, has developed a device known as a fused cutting-machine connector, made in any amperage for use on 250- and 500-volt circuits. The connector is of an unusual design, arranged so that it can be easily attached to the machine circuit or the trolley wire simply by turning the handle, this having a tightening effect on the clamp and giving a contact surface of about 3 in.

In cases where the connector is attached to the trolley wire it allows sufficient clearance for the locomotive to pass under it without removing the connector from the wire. Another rather convenient feature is the fact that in cases where it is necessary to run the mining machine cable under the track a plug connection at the end of the connector can be removed, thus eliminating the necessity of cleaning under the track sufficiently to allow the whole connector to pass, this plug connection being just slightly larger than the diameter of the mining-machine cable.

The connector is of rugged construction and is unaffected by moisture. The case is of the highest grade bakelite and the metal parts are of a high grade bronze, thus insuring proper insulation and maximum current-carrying capacity. A large disk on the handle prevents the operator's hand from slipping onto the metal parts that are not insulated.

The connector is equipped with a Trico fuse link and a case, thus insuring long life to the fuse compartment—eliminating practically all carbon de-

posits from the inside of the case and the possibility of leakage. The fuse case is so arranged that the machine operator cannot easily insert anything but the proper fuse.

The connector can be attached to the mining-machine cable with little or no expense by simply soldering the charged side of the cable into the lower plug terminal of the connector. It is also arranged with a glider to be used when traveling from one cutting place to another. The head of the clamp is drilled to receive a 4/0 wire, the wire being held into the connector by a set screw, thus making it easy to replace the glider. The fuse case is properly ventilated, eliminating the possibility of its exploding in the operator's hand.

Expensive mine fires are frequently caused by mining-machine cables becoming so greatly overheated that they cause fire. There is in general use today an all-rubber insulated mining-machine cable, which being expensive might well be given the protection that this cutting-machine connector will afford.

This connector also protects the mining machine and the machine operator. It eliminates the line contact made by the rather crude hook, which has been used for so many years. Compensation laws require a fused connection on the end of trailing cable and if such a connection is not used the mining company is liable to an increased charge.

### Trolley with Ball-Bearing Pressed-Steel Wheels

A new trolley, the distinctive feature of which is that it has ball-bearing pressed-steel wheels, has been brought out by the Chishold-Moore Mfg. Co., Cleveland. The bearings are built in the wheel during its manufacture, so that the wheel and its bearings form a complete unit. The wheel is of 3-in. diameter and has a  $1\frac{1}{8}$ -in. tread.

The side frame is of steel and has an oscillating feature to distribute the load on all four wheels and thus assure positive traction. By the shifting of washers the trolley may be used for 4- to 7-in. I-beams and by the use of special separators it can be operated on larger beams. A hoist with swivel connection when hung from this trolley can swing a complete circle. When an I-beam is closed at both ends the trolley may be installed quickly by removing the equalizing pin shown in the lower part, thus separating the two side frames.

It will be noted that the trolley is simple in construction and convenient to install. It weighs only 17½ lb. complete. It is made at present in one size to handle loads up to 1 ton.

**Adjustable Hoist Trolley**

Ball-bearing wheels with bearings built into the wheels makes this trolley operate easily even under full load. This makes it an ideal outfit for machine shops and store rooms.

### Wheel with Double Tread

A wheel designed with a double tread to run on rails or flat surfaces is being manufactured by the Vulcan Iron Works, of Wilkes-Barre, Pa., for sale by the Griffin Double Tread Wheel Co., 27 William St., New York. The illustration shows the wheel with a section cut out. It is made in the usual diameters and weights depending upon the service for which it is to be used.

This wheel can be made from open-hearth steel or chilled steel made by the Griffin process. The manufacturers claim that the sections can be made as thin as the ordinary wheel and yet have sufficient strength.

On specially designed trucks, brakes may be applied to bear directly on the metal surface of the inner or rail tread. The flat large diameter tread is covered with a rubber tire. By the use of this wheel, it is easy to transfer from a rail to a floor or vice versa.

**Wheel for Operating on Rail or Flat Surfaces**

Wherever the distance between the top of the tie and the top of the rail is sufficient, this wheel can be used on either rails or flat surfaces. Such a wheel will no doubt find application in mine repair shops and foundries.

**Special Protective Connector for Mine Cables**

Many of the more serious delays to electric equipment in the mines are due to mining machine and drill machine cables being grounded. This clamp is designed so that an efficient connection can be made to the trolley wire. A fuse in the handle protects the equipment working from the cable circuit and also eliminates dangers to the workmen.

# COAL AGE

McGraw-Hill Company, Inc.  
James H. McGraw, President  
E. J. Mehren, Vice-President

Devoted to the Operating, Technical and Business  
Problems of the Coal-Mining Industry

R. Dawson Hall  
Engineering Editor

Volume 26

NEW YORK, JULY 17, 1924

Number 3

## Fourth Annual Model Mine Number

NONE of the bituminous coal companies of the United States can lay claim to producing more than 3 per cent of the country's output of soft coal. The Glen Alden Coal Co., however, during the year 1923, produced somewhat over 10 per cent of the total output of the anthracite region, thereby supplying approximately 800,000 families with domestic coal in addition to furnishing steam coal for numerous industries throughout the eastern and middle western parts of the United States. Nearly twelve miles of railroad cars are shipped daily from its various operations. It normally carries 20,000 names on its payroll.

The Glen Alden Coal Co. began operations as a successor to the Delaware, Lackawanna & Western R.R. Coal Department on Sept. 1, 1921, at which time W. W. Inglis, who prior to that time was vice-president and manager of the Delaware, Lackawanna & Western R.R. Coal Department, was made its president, and Shelby D. Dimmick, who prior to that time was assistant to the vice-president and manager, was made its vice-president and general manager.

The property of this company is situated within Lackawanna and Luzerne counties, there being seven collieries in each county. Tributary to these fourteen collieries are many mines which, in years gone by, were separate and distinct operations. By consolidating a number of local collieries into one, the Glen Alden Coal Co. has effected appreciable economies. Of these fourteen collieries, four during the past year produced over one million long tons of coal each.

At the present time, twelve separate coal beds are worked by the Glen Alden company, the number operated by the various collieries ranging from three to eleven. The number of mines tributary to the different collieries of this company, the number of beds worked at each colliery and the revenue output produced by each during the year 1923 are shown in the table.

Naturally a company of this size arouses no little interest as to its methods of operation. As little has hitherto been written, *Coal Age* in this number gives a general review of this property, elaborating on the Baker Colliery which is its most modern and important development.

To those who have been associated with the anthracite field sufficiently long to observe the

changes that have taken place in this industry' modern equipment like the Baker Colliery will be recognized readily as being as much a revolution in anthracite mining as is the modern trans-Atlantic steamer from the sailing vessel that plied the ocean lanes when the anthracite industry was at its beginning.

Much has been said by the newspapers of the country during the past ten years regarding the constantly rising price of coal. Little do the readers of these periodicals appreciate the fact that were it not for such modern equipment as is typified by the Baker Colliery, the prices of anthracite would be far beyond the figures now made necessary by constantly increasing labor costs and the growing difficulty of mining. The Glen Alden Coal Co. is a pioneer in the electrification and mechanization of coal properties. Its progressive policies have fully justified its selection of this periodical for treatment in its fourth annual model mine number.

The officers of the Glen Alden Coal Co., to whom credit for its progressive operations is largely due, are: W. W. Inglis, president; Shelby D. Dimmick, vice-president and general manager; G. N. England, secretary and treasurer; James Dodson, assistant secretary and treasurer; Bradford Samson, assistant to the vice-president and general manager; Charles R. Seem, electrical engineer; N. N. Nichols, chief mining engineer; Charles St. John, mechanical engineer; Frank Hildebrand, auditor; J. N. Shaw, purchasing agent; and J. H. Oliver, general counsel. John R. James is the colliery superintendent of the district tributary to Baker Breaker.

Glen Alden Output and Where It Comes From

County	Colliery	No. of Tributary Mines	No. of Beds Worked	Revenue Output in 1923 in Long Tons
Lackawanna	Storrs.....	2	11	1,040,810
Lackawanna	Diamond.....	2	11	605,585
Lackawanna	Hyde Park.....	3	4	499,900
Lackawanna	Archbald.....	1	5	442,623
Lackawanna	Pyne.....	1	5	458,749
Lackawanna	Taylor.....	3	6	677,043

Luzerne	Avondale.....	1	3	299,669
Luzerne	Loomis.....	2	4	1,255,295
Luzerne	Truesdale.....	2	9	1,270,759
Total.....				10,182,769 or 11,404,702 short tons

## Do You Know or Merely Suppose?

**F**EW HAVE decided just how many men are needed in any one section of a mine or at any one mine to produce any given tonnage. At one plant the foremen and section foremen met and decided, with the assistance of the management, just how many men were needed in each of the major divisions of the mine. Comparisons between sections enabled a labor budget to be planned and, when it was decided, the sections were restricted to just that number of men. The number was not finally decided at a single meeting. It took two or three sessions and some discussion, but at last a labor budget was fixed, and the foremen were obliged to conform to it. The company found that it reduced operating costs immensely.

## The Public Generalizes

**O**NLY A CLEAR case is a good case. No one can clear himself effectually who needs a lawyer, an accountant and a mathematician to do the clearing. A maze of figures scares the public. That is why wise men leave figures out of their editorials. The public does not pick up the paper usually to make complicated calculations.

Our coal case has been complicated by the troubles of the retailers. As shown in another section of this paper the wages of wharfmen and teamsters in Boston have much more than doubled. The increase in wages of those employees in 1920 and 1921 outstripped the cost of living. Since then living costs have declined, but the wages of wharfmen and teamsters have not fallen in proportion.

The domestic consumer makes no fine distinction between mines, railroad and retailer. They are all one to him. It is a folly to forget that they are all part of the coal family. The railroads stand a little apart because they are not engaged solely in the transportation of coal. But the operator and retailer are in a real sense one. They come alike under the ban of the public when the public is displeased about coal. The retailer has a right to concern himself with costs and quality at the mine and the operator with costs of distribution and quality of coal as delivered to the consumer. Both also are interested in railroad transportation.

Lower costs to the consumer by the payment of reasonable wages, by efficiency, by a reduction in the wastes of competition are matters of interest to the whole industry. The excessive increases in wage in all three industries, due largely in the case of mining and transportation to government interference, has placed a burden on the coal consumer against which he is revolting. The operator should bear that fact in mind and let the public know that coal at the mine, coal on the railroad and coal in the delivery truck are, one and all, paying excessive wage bills.

The decline in the roadbuilding and house-erecting industries will probably correct this anomaly in the wages of wharfmen and teamsters before long and may make the consumer's bill a little lower, thus relieving the anthracite operator of some of the opprobrium that accompanies high prices. It is interesting to note what generous increases the wharfmen and teamsters have received as compared with those of the men in the building trades. The public too often overlooks the fact that the mechanic or alleged mechanic in the

building trade always has received wages above the average and consequently the present wages are relatively not much out of proportion to former wages, when the cost of living is considered. Even, at that, the wages of all construction men are due for a heavy decline.

## Electricity as a Simplifier

**W**HAT is said about the Baker breaker in regard to electricity is true not only of breakers but of the underground. The simplicity of that building is largely due to the absence of mechanical drives. In past generations the breaker was full of ropes, even today in a few breakers some still remain. They strain the structure, they shake it and they add somewhat to the hazards of operation. Furthermore they interfere with design.

Still worse would be the complication underground if the mine were operated by rope drives. We can hardly conceive of setting a hoisting engine at the top of a shaft to operate a tail-rope haulage underground. But this must be done if the mine is to be operated without electricity and all of four substitute plans are rejected, none of which are as convenient as the electrical method. A steam engine could be placed below ground at each level to operate a hoist. An air engine could be used for the same purpose, pipes being carried down the shaft. Compressed air at high pressure could be piped to a point underground and fed to a compressed-air locomotive, or animal power could be used.

In some metal mines steam engines are placed below ground. Temperatures of 130 deg. are common. What it means, even in the dry air of Arizona, to work at such a temperature can be imagined. Fortunately only at odd times does a steam engineer actually have to work, but to stay in a place having such an excessive temperature is extremely enervating.

The loss in steam pressure in such installations is immense and the dangers of fires in any but a fire-proofed shaft is extreme, for not only is the heat for combustion provided by the pipes but the draft to fan any combustion into flame is also afforded. The loss of air pressure when an air-driven hoist is set below ground is deplorable and the pipes, that lead the air to it, must be of large diameter and thus cumbrous and space filling.

The compressed-air locomotive is more feasible and is used in some mines. Animal haulage is, of course, taboo. How feebly all these expedients compare with electricity as an agent for underground service! Nothing has been said as to pumps and auxiliary fans, but with them also the argument in favor of electricity is equally strong. In fact, electricity it is that is making compressed air underground feasible. The compressor is placed in the mine and is driven electrically. Thus, what compressed air can do best in the way of percussion and shovel operation it can be permitted to do, and it will not be hampered by difficulties of transmission.

Electricity has been the great simplifier of mine operations from face to breaker or tippie. Just think what a mess of ropes we would have if we tried to cut, load, transport as well as hoist coal by ropes and to pump by similar methods. A little consideration of this fact and it will be easy to understand why electricity has made such rapid strides. The mining industry above as well as below ground could not do without it.

General View of Storrs Colliery.

## Glen Alden Operates Three Longwall Faces with Conveyors in a Thirty-Inch Coal Seam

Mining Methods That Presage Company's Ability to Mine Thin Coal Whenever Big Seams Begin to Fail—Company Mines Eleven Seams but Not All at Every Property

BY FRANK H. KNEELAND

Associate Editor, *Coal Age*, New York, N. Y.

CONVEYOR mining methods are not new in the anthracite region whatever they may be in bituminous. The region that invented and fathered the scraper had conveyors many years before the West Virginia Coal & Coke Co. tried its experiments.

Little has been said about the Glen Alden Coal Co.'s face conveyors and longwall methods. Most persons believed the company had stuck uncompromisingly to room-and-pillar workings, electric and mule gathering methods, chutes and full batteries. But the Glen Alden has been doing a little pioneering of its own in hunting for a way to mine thin coal to maintain its large output.

Just a word about the seams in the Glen Alden mines prior to a description of its mining methods. In Lackawanna County the beds worked are as follows: The 8-ft. or Olyphant No. 1, the 5-ft. or Olyphant No. 2, the 4-ft., the Diamond, the Rock, the Big or 14-ft., the New County or Marcy, the Clark, and the Dunmore Nos. 1, 2 and 3. In Luzerne County the beds worked include: The No. 5, the Snake Island, the Abbott, the Mills or Kidney, the Hillman, the Baltimore, the Forge, the Twin, the Ross and the Red Ash. In some operations some of these beds are divided forming two or more workable measures. Thus in some localities the Baltimore bed is split into an upper and a lower measure called respectively the Cooper and the Bennett beds.

The thickest coal now worked occurs in the Red Ash bed at Avondale, but the Baltimore bed at Bliss colliery is about equally thick. The thinnest coal is found in the Dunmore No. 1 and New County beds at Diamond colliery, the thickness of these measures being about 30 in. Beds of this thickness cannot, under present conditions, be worked by themselves at a profit. It is

only when such measures occur near thicker coals that can bear a portion of the expense of their operation that it is permissible to mine them.

In most places the coal beds worked are both overlaid and underlaid with hard rock which renders either the brushing of top or the lifting of bottom difficult and expensive. The coal pitches at all angles from horizontal to vertical. On the other hand, considering the reflex folding of the measures, it is often said that the pitch is more than 90 deg.

The methods of mining in any section of the mines vary greatly with the pitch of the measures at that point. As a rule the coal is mined by room-and-pillar methods. On pitches not exceeding 15 to 18 deg. cars are taken to the room faces by means of room hoists. On steeper pitches varying from this inclination up to about 40 deg., sheet-iron chutes are employed. On steeper slopes coal is broken down into full batteries or rooms. In low flat beds the Strange scraper serving three to five rooms is being used with much success.

At the Dodge slope of the Baker colliery an undercutter is in use in conjunction with a face conveyor. This mining machine makes an undercut 5½ ft. deep on a continuous face 220 ft. long which constitutes approximately a full shift's work in this coal. In the bottom at this point are small hummocks or knobs that the cutter bar encounters. These make cutting difficult. Machines have never been used in these mines on grades exceeding about 5 deg. Scrapers, however, have been employed on pitches up to 20 per cent.

In shooting coal it has been found best to follow the directions of the explosives' manufacturer. On the other hand the miners insist on doing about as they please. Actual practice with the use of explosives therefore varies greatly with conditions. Under ordinary circumstances the miner shoots the face of his chamber much as a contractor blows the face of a rock

NOTE—The reader will not fail to observe the multiplicity of buildings and other structures including reservoirs in the illustration of the Storrs Colliery, which forms the headpiece of this article. Hard coal as it comes from the mines is not salable; it must be manufactured or as it is commonly expressed "prepared for market."

tunnel except that fewer holes are used. In most cases four shots are enough to bring down a face. The coal is more or less distinctly stratified and some vertical-cleavage faults and slips are also present.

Much coal drilling is being done by hand percussive drills of the jackhammer type. These are purchased by the miners and paid for in monthly installments deducted from their wages.

Coal is mined in almost every instance by room-and-pillar methods, the rooms being normally driven from 20 to 30 ft. wide depending upon local conditions. Wherever possible all unburnable material is left in the room. Sometimes, however, it is cheaper to bring it to the surface than to stow it underground.

As a rule central compressor plants are installed on the surface, and the air is piped underground to the point of use. Small local air compressors, electrically driven, are also sometimes installed underground. Air lines from central plants are seldom over 4,000 to 5,000 ft. long. Screwed joints in such lines are red-leaded and are kept tight by frequent inspections.

In all recent mining operations ample pillars have

able intervals. When the point is reached where it is desired to start a longwall face a "doghole" 16 ft. wide is turned from the side of the entry away from the aircourse. Coal is shot from the solid until the recess is 10 ft. deep. The undercutter is then put into the place thus formed and successive cuts taken until the doghole has been advanced to a depth of 35 ft., the coal meanwhile being reshoveled to the gangway.

The head and tail sections of the conveyor are next connected up in the doghole and succeeding cuts conveyed to the gangway. At every third cut a section of conveyor is added to that already in place. This is installed next to the takeup section. That is, at every third cut the takeup section is disconnected and drawn back to the face and another length of plain conveyor put into place between it and the rest of the conveyor already in position. In this manner the face is advanced until the doghole has attained a depth equal to the length of longwall face desired.

In this mine three such faces are at present worked—one 220 ft. long, another 175 ft. and the third about 160 ft. As the operation of all is exactly similar,

FIG. 1  
Conveyor  
Discharge

This shows the delivery end of the coal conveyor extending from the side of the heading over a partly loaded mine car. The coal cutter also appears in the position it occupies at the end of its face cut. The timbermen turn this machine sidewise, that is, lengthwise of the face and utilize its power in pulling the conveyor over to its new position. The undercutter thus serves two purposes.

been left to insure adequate surface support. The width of pillars is increased with the depth of bed worked.

In the second mining of flat beds, the pillars are usually drawn by men working at their inby ends. The pillars in the beds which pitch heavily are removed either by skipping or by splitting. Where the pillars are wide they are split and the pillars on either side are worked at such an angle that the coal will flow toward the center of the split. Where the pillar is not wide, skipping replaces splitting.

Reference has already been made to the mining machine and conveyor workings in the Dodge Slope. The average thickness of the coal worked at that point is 30 in. As the method employed in extracting this bed is peculiar to this mine a somewhat detailed description of it is perhaps justified.

To begin with, a 16-ft. main entry is driven in the coal. Parallel with this main entry and separated from it by a pillar 12 ft. thick a ventilation entry or air-course is driven. This entry is made 12 ft. wide with 12-ft. crosscuts between it and the main entry at suit-

attention in this description will be confined to the 220-ft. face. The number of shovelers employed and the tonnage of coal produced will depend, of course, directly upon the length of face worked.

When the doghole has been driven to the desired depth a slabbing cut is taken by the mining machine along the entire length of its inby rib, this cut being made from the inner to the outer end. The coal is then shot down and loaded onto the conveyor which delivers it to cars on the entry.

After a slabbing cut of this kind has been loaded out the timber gang comes in. This gang consists of a chargeman or miner and four laborers. They first turn the coal cutter, which has been standing beside and parallel with the entry, into a position parallel to the new face and close to it. A hitch is then taken on the conveyor with the main or lead rope or chain of the machine. The delivery end of the conveyor is thus pulled over 5½ ft. toward the coal by means of the machine. The men, however, assist in this operation by using crowbars at various points along the conveyor.

Fig. 2—Storrs Breaker, Glen Alden Coal Co.

Steel, concrete and glass are the accepted materials of breaker construction today. This is also true of most other mine buildings. Note the transformers and the transmission tower in the foreground. Electric current has practically supplanted all other means for energy distribution except for short distances, where belts are often employed.

The coal cutter is then moved (under its own power) back along the face for a distance of about 55 ft. and another hitch taken on the conveyor. This operation is repeated four times or until the coal cutter has been moved to the inner end of the coal face and the conveyor has been pulled into its new position and properly lined up about 7 ft. from the face.

The conveyor is now started but with its direction of travel reversed, that is with the upper strand moving inward or away from the entry instead of outward toward it. Round timbers in lengths of 4 ft. are next loaded into the conveyor from cars on the heading. These are removed from the conveyor at intervals along its length and laid to one side to be used in building cogs for roof support. About five mine-car loads of this cog timber and one carload of props are needed for each 5½ ft. advance of the face.

After enough timber has been spotted in this way, cogs are built, three timbers to each layer, on 8-ft. centers in a direction parallel with the face and on 5½-ft. centers in a direction at right angles to it. Props are set alternating with the cogs in the rows parallel with the face, except that no props are set immediately beside the heading. On the side of this passage, therefore, single cogs alternate with double ones. The entire arrangement is shown in Fig. 3.

After cogs and props have been put in place and securely wedged against the roof the machine runner and his "kailer" or helper, begin the new cut at the inner end of the face. This is made in a small parting that occurs in this bed about 6 in. from the bottom. A miner follows the machine setting props, usually about 6 ft. apart but closer if roof conditions require. This row of props is about 5½ ft. from the face.

Another miner and his helper follow the prop setters drilling and charging the shotholes necessary to bring down the coal. These are usually about twenty-two in number. They are made 1½ in. in diameter and 5½ ft. deep. Each is loaded with 2½ sticks of 1-in. Red Cross low-freezing dynamite. Just enough tamping is used to hold the charges in place.

On this 220-ft. face thirteen loaders are employed so that each has about 17 ft. of face to clean up. Inasmuch as the places near the far end of the conveyor are preferred to those near its discharge end (because the conveyor is loaded progressively from its rearmost end to the heading and because the man at or near the farther end, having an empty or nearly empty conveyor to shovel into, can clean up his allotted 17 ft. of face somewhat quicker than the man near the heading who must shovel to the conveyor when nearly full) the men rotate in their positions from day to day. In other words they change places exactly as did the scholars in the old-time spelling class when nobody missed a word and he who was head of the class today took position at its foot tomorrow.

In coal as low as 30 in. the men necessarily must work on their knees. As a result the shovelers as well as all others employed on these long faces wear heavy knee pads made of short sections cut from automobile tires. These are almost ideal for the purpose and afford thorough protection from the small coal and rock on the floor. In addition, however, some wear secondary or auxiliary pads of cotton sewed to their trousers legs.

The shovels used in this low coal are nearly straight, the angle between handle and blade being very small. To be exact No. 3 scoops with No. 1 lifts are used. After the loose coal brought down by the regular shots has been loaded out a "plugger" or miner straightens out the face by shooting off any projections that may remain upon it. The shotholes drilled in this work are

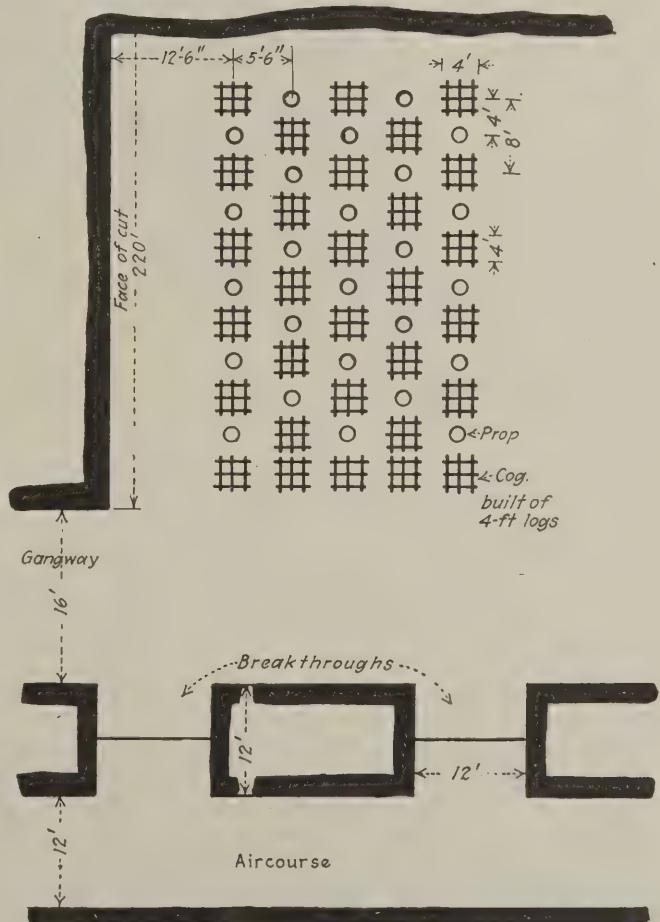

Fig. 3—Diagram of Longwall Face

This diagram, necessarily, is not drawn to scale. With a heavy brittle cover, roof support is the great problem encountered. Cogs and props are used in abundance and together control the settlement of the roof as long as necessary for the safe extraction of coal from the face.

**Fig. 4—Shoveling to the Conveyor**

This picture was taken from the heading. It shows one of the shovelers on his knees loading coal into the conveyor. This conveyor consists of a low, shallow, flaring trough in the bottom of which a chain with low flights or crossbars is drawn along. Being built in sections it may be readily transported over either short or long distances.

seldom more than 2 ft. deep, and the charges of explosive used are correspondingly light.

At 2 p.m. the timber gang arrives, and the cutter is ready to start his machine by 10 p.m. The cut is usually completed about 4 a.m. The chain on the mining machine carries thirty-eight bits in seven positions. Bits are changed three times in making a cut.

**FIG. 5**  
**Truesdale**

This is one of the largest collieries in the anthracite region. Again note the many structures of varied type, yet all built of substantial materials.

Shortly after the machine has finished its cut the coal is shot down. The smoke clears away rapidly, and the work of loading out usually begins about 6 a.m.

All bone is left in the face by the loaders. The timber gang throws this material into the gob between cogs. A space 2 ft. wide is left between the conveyor and the face of the first row of cogs. Coal falling from the edge of the conveyor into this space is cleaned up by the loaders before they leave.

The loading crew consists of thirteen laborers who shovel to the conveyor, three men (miners) on the gang-

way and one plugger. One of the gangway men helps the plugger after the work has well started. The afternoon shift or timber gang consists of one miner and four laborers. The cutting or machine crew is composed of one machine runner, one helper or "kailer" and one miner who sets props after the machine. This crew is followed immediately by one miner and one laborer who drill, charge and blow down the coal. One foreman has general charge of all machine faces.

Every 5½-ft. cut on a 220-ft. face yields in coal of normal thickness about fifty-two mine-car loads. If the bed thins to any appreciable extent only fifty to fifty-one carloads are obtained.

When the longwall face on one side of the heading has been worked to its limit advancing, a second face is opened on the opposite side of the heading, and the coal on that side recovered in retreat. This second or retreating face necessarily extends across the aircourse previously mentioned. This, however, does not in any way interfere with operation.

Thus in brief has been described what is one of the most interesting mining methods in the entire anthra-

cite region. In an industry as inherently conservative as that of coal production success has not been attained without difficulty. And the obstacles encountered have not been confined to trouble from roof, floor, caving or machinery but have embraced the set habits of thought, the mental inertia of those engaged in the industry. The fact that this method of mining has been successfully adopted and that excellent team work now exists among the individuals and gangs employed speaks volumes for the zeal and perseverance of the officials who had the vision to perceive its possibilities.

**FIG. 6**  
**Sugar Notch**

A heavy articulated trolley locomotive taking a long trip of loads to the breaker. Glen Alden has approximately an aggregate of 500 miles of track at its mines under and above ground and an electric locomotive for each mile of track. A mining company as large as the Glen Alden Coal Co. has a trackage greater than some sizable railroads.

**Major W. W. Inglis**

*President, Glen Alden Coal Co.*

**S**HEER merit placed W. W. Inglis in the position of president of the Glen Alden Coal Co. In the undistinguished beginning of his career he was not a Glen Alden attaché, but an office boy for the Hillside Coal & Iron Co., an affiliation of the Erie R.R. He received the job April 1, 1884. By 1890 he was chief clerk, and in 1901 superintendent. Within a few short months, Sept. 15, 1902, he was made superintendent of the Pennsylvania Coal Co., an affiliated organization, but having more than twice as many mines and four times as many employees as the Hillside Coal & Iron Co. In 1909 he became superintendent of both companies and in 1913 he became general manager.

On Feb. 21, 1916, the Delaware, Lackawanna & Western R.R., reversing its general practice, went out of its organization to find a general manager for its coal department. Major Inglis was appointed to take complete charge of its properties. Since then he has become president and

the mines have become divorced from the railroad, the new company's name being the Glen Alden Coal Co. Major Inglis earned his title by service in the Pennsylvania National Guard and by active service in the Spanish-American War. Those who served under him recall with much pleasure the time spent under his command.

Major Inglis entered the business of coal production from the office, but let not that deceive anyone. Mr. Inglis is not deskbound in any sense. His delight is to follow out the details of mining and preparation; and the changes in methods of operation in the collieries under his control bear ample witness to the fact that he has the engineering problems of mining always before him, all the designs of the engineering department receiving his inspection and signature. He is "everlastingly at it" like the rest of his staff and finds nothing more pleasurable and inspiring than the task of making Glen Alden a profitable, economical, substantial coal property.

*Panoramic View of Baker Colliery*

**D**IN, DIRT, disorder and vibration formerly marked the anthracite breaker. The old-time coal breaker impressed and pleased the visitor by its size, but it appeared a sinister blot on the landscape and was an unpleasant place in which to work. It seemed almost a joke to describe it as a structure where coal was cleaned so grievously was it in need of that process itself. But modern methods of routing material have simplified this structure as they have the mills at the metal mines, and the modern breaker cleans and sizes coal so systematically and so simply and withal with such a little dirt and disorder that it can be entered without fear of soiling one's clothes.

The Baker breaker of the Glen Alden Coal Co. is kept as clean as a kitchen. The abundance of light makes it easy to ascertain just what results are being obtained. The old way of taking a handful of coal and carrying it to the uncertain light of a grimy window has passed with the age of darkness, and today it is easy to see the effect of each process at the point where it is performed.

#### ALL SIZES OF COAL CLEANED IN JIGS

In the Baker breaker the coal is crushed in a building near the ground level and then elevated to the top of the main building by means of a conveyor. Thereafter the coal passes by gravity through the various simple stages which convert it from a product of mixed size and mingled impurity to a carefully cleaned coal of eight sizes, all the grades, no matter how fine, being jigged free of impurity. The main rolls are placed on the ground level. Consequently the only vibration perceptible in the breaker is that due

NOTE—In the headpiece the foot house with the headframe may be seen on the extreme right. Next comes the long housed-in conveyor that may be seen leading to the top of the breaker. That the movement of material is an important operation at this colliery may be judged from the number of conveyors appearing in this picture.

## Baker—The Latest

Reaching the Breaker from  
on the Ground Level and the  
the Building—Simplicity and

to the jigs and shakers, and even this is reduced to a minimum by balancing; that is, by so arranging the equipment that the action of one machine, or part of a machine, tending to cause vibration in one direction is counteracted by another machine or another part of the same machine, which tends to cause vibration in an opposite direction. Sturdy construction and the use of separate drives for the larger units also do much to insure steadiness of the building.

Gone are the long ropes and the big driving belts that used to clutter and cumber the breaker, interfere with its rigidity and defeat any attempt to create order out of chaos. Electrical power is transferred from point to point by almost invisible conductors which can be made to follow the lines of the building and thus to perform their function without hindering the emplacement of machinery. The multiplicity of drives made possible by electric power has by the avoidance of synchronism made it possible to operate a breaker with minimum vibration. The old breaker was never a show place. The Baker breaker, on the other hand, is always in such order that it is ready for visitors. The attendant with his dust cloth and his O-Cedar mop sees to that.

Baker breaker is located on the outskirts of Scranton. It is a concrete, steel and glass structure throughout. In this breaker and adjacent buildings and structures a total of 4,773,800 lb. of structural steel and 44,666 sq.ft. of smooth wire glass were used. All machinery in the building is electrically driven, the larger units being fitted with individual drives and many of the

Product Elevated to the Top of  
Neatness Foster a Good Morale

smaller machines or those requiring less power, such as the jigs, are driven in groups from line shafting. Steam from the boiler plant is used for heating, as may be judged from some of the accompanying photographs showing literally miles of pipe used in the heating coils. A small electrically-driven vacuum pump sucks the air from this heating system, and all condensate from it is collected and returned to the boiler plant.

Fig. 1—Trip Haul Feeding Cars to Dump

By means of this car haul the one man shown feeds the cars one at a time to the dump. The lever that the man is holding operates a friction clutch by means of which movement of the chain is controlled. This machine is driven by a motor in the small shed at the right.

Coal reaches the Baker breaker from several separate sources, namely: From the Dodge shaft, (1 on the flow sheet, Fig. 2), from the Bellevue slope (2), and from the Bellevue shaft (5). Coal from the Dodge shaft is brought to the loaded yard in trips each of about forty cars by electric trolley locomotives. Here it is joined by coal from the Bellevue slope which has been hoisted in trips each of four cars.

When a locomotive arrives in the loaded yard with a trip from the Dodge shaft it uncouples from its trip and shifts to the loaded track whatever loads from the slope may be waiting, returning any empties from the slope that may be ready. Cars from these two sources are of slightly different design, one end-gate of the slope cars being a little higher than the corresponding end of the shaft cars, so that they easily may be distinguished and switched to different empty tracks. After properly placing these cars, both loads and empties, the locomotive is coupled to a trip of shaft empties and returns to the mine with them.

An electrically driven tripmaker (3) feeds the loaded cars to the steam dump (3a) which discharges to a chute leading to the dragline conveyor (4). The tripmaker or car feeder (3) as may be seen in Fig. 1 consists of a strand of chain provided with lugs engaging the cars on the loaded track. This chain is driven through back gears and a friction clutch by a 50-hp. induction motor operating at 600 r.p.m. By manipulating the friction-clutch lever, therefore, the dumpman may feed cars to the dump as slowly or as rapidly as he pleases. About 600 cars are passed over this dump daily.

After being discharged on the steam dump (3a) the cars pass through a kickback and gravitate to the empty yard. As previously stated cars from the Dodge shaft are switched to one track and those from the Bellevue slope pass to another. Cars hoisted from the Bellevue shaft discharge to the same chute, (4a),

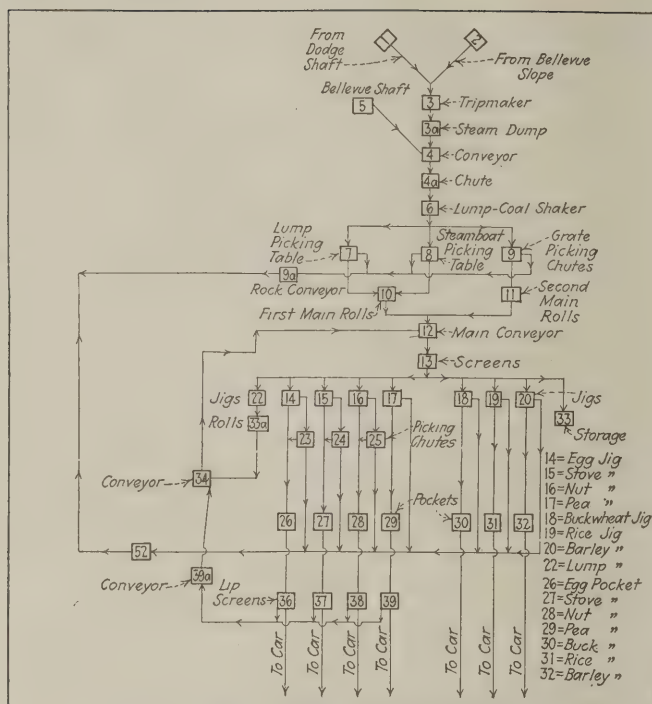

Fig. 2—Flow Sheet of Baker Breaker

This diagram is intended to show the origin and movement of the coal. It is strictly diagrammatic no attempt having been made to show anything other than the sequence of operations through which the coal passes.

that receives the coal from the conveyor (4). This chute leads to the foothouse.

Within the foothouse coal from all three sources (the Dodge shaft and the Bellevue shaft and slope) is discharged to the lump shaker (6). This machine is of somewhat unusual construction. It consists of two real and one false deck. That is the upper deck is short and unperforated and serves only as a reciprocating feeder to the other decks. This shaker separates the coal into three sizes, into lump, into steamboat and into grate and smaller.

From this shaker the lump passes to the lump picking table (7). The steamboat size likewise passes over a picking table (8), and the smaller coal is picked in the chute (9). Rock separated from the coal on the picking tables or in the chute is thrown into the rock conveyor (9a) discharging to the rock conveyor (52) leading to a conveyor (53 not shown) by which it is discharged to the dump.

Fig. 3—Drive of Conveyor to Foothouse

The head sprocket is driven by gearing from both sides. As may be seen all dangerous moving parts are thoroughly boxed and railed in, protecting the workmen from getting caught and being injured. Glen Alden believes in safety as well as neatness.

From the picking tables (7) and (8) the coal goes to the first main rolls (10). These are the largest in the anthracite region measuring 60x60 in. They are shown in Fig. 4 and are belted and backgeared to a 75-hp. motor that also drives the picking tables. These latter are of the pan-belt type, 4 ft. wide and set on an inclination. Grate coal from the picking chute goes through the second main rolls (11).

#### WHEN CRUSHED ALL COAL GOES TO TOP OF BREAKER

After crushing, coal from both rolls as well as the smaller material that is bypassed around them, goes to the main conveyor (12) leading to the breaker. This conveyor is of the dragline type, 5 ft. wide. It is driven from the top by a 300-hp. motor through a silent chain and a double spur-gear reduction. This motor and driving mechanism is shown in Fig. 5.

At the top of the breaker the coal is discharged from the main conveyor onto the screens (13). Here it is separated into the various market sizes, the egg passing to the egg jig (14) the stove to the stove jig (15) and so on, the barley jig being (20). Each jig is provided with a storage hopper or reserve pocket, assuring a

Fig. 4—Main Rolls in the Foothouse

These are the rolls that crush down the larger lumps. A smaller set of rolls located near them crushes the smaller lumps while coal of egg size and smaller is bypassed around both sets of rolls. To send coal already small enough to be marketable through rolls would result in needless degradation.

supply of coal to the jigs at all times. Buckwheat No. 4 is sent to the storage (33) and is ultimately sold for the manufacture of briquets.

Oversize coal or that larger than egg is first passed through the oversize jig (22) and then through the crusher (33a) whence it is sent back to the main conveyor (12) by way of the conveyor (34). Refuse from the egg, stove and nut jigs is hand-picked in the slate chutes (23), (24) and (25), the good coal being thrown into the chutes leading to the pockets. Refuse from all jigs passes to conveyor (52) going eventually to conveyor (53) which discharges to the rock dump.

From the jigs the coal goes to the pockets (26) to

FIG. 5  
Main-Conveyor  
Drive

This is the conveyor that brings the coal to the top of the breaker. The first speed reduction from the motor is made by means of a silent chain; succeeding reductions are by spur gears.

(32). From these it is drawn off to railroad cars, the larger sizes going over the lip screens (36), (37), (38) and (39). Lip screenings are returned to the breaker for reparation by means of the conveyors (39a) and (34).

In all twenty-one Elmore jigs are installed in this breaker. These are driven by four 75-hp. motors through line shafts. These shafts are carried on pedestals from the floor, and one of them is mounted on roller bearings. This roller-bearing installation is in a degree experimental and the results obtained from it

Fig. 7—Line Shaft Driving Jigs

Here again pulleys, couplings, belts and the like are carefully railed and boxed in to protect the workman. These protective devices are investments in safety that pay big dividends.

be flushed into the dip workings of the mine. A large area over old workings will thus be supported effectively.

The water used in the jigging and other preparation processes in this breaker is brought from the mine. After use it is sent to a settling tank of 500,000-gal. capacity located beside the breaker. The mine water

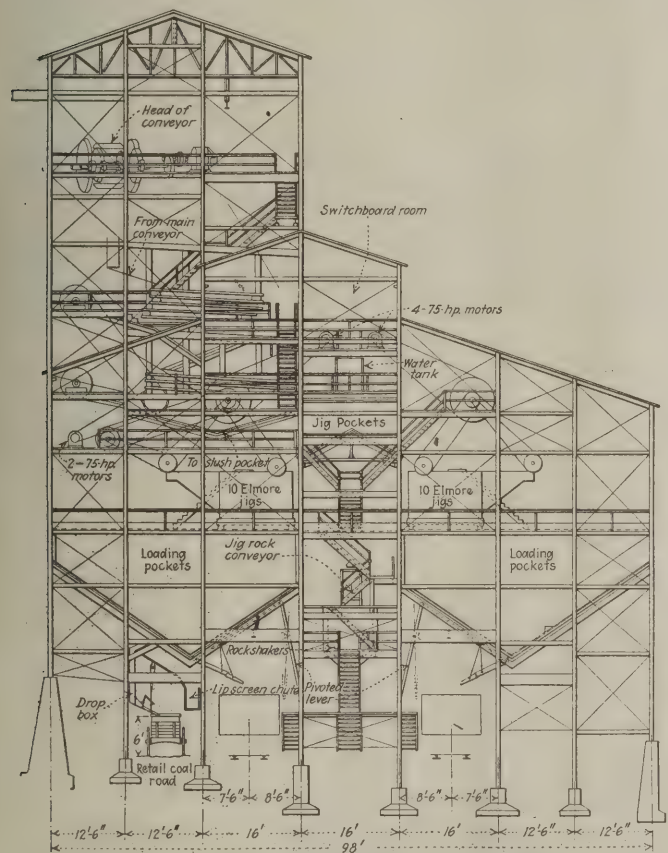

Fig. 6—Cross-Section Through the Breaker

This shows the relative positions of some of the machinery. Jigs are arranged on two sides of the building and driven in groups from line shafts. This affords a symmetrical arrangement of this machinery.

will doubtless determine the company's policy regarding similar installations in the future.

Plans have been completed for the installation of a rock crusher to which all rock separated from the coal during preparation will be delivered. This will be crushed to suitable size and transported to a borehole near the man-and-material shaft, down which it will

Fig. 8—Piping System Supplying the Jigs

Inasmuch as the water is used over and over again it becomes highly acidulous. Accordingly cast-iron pipe is used, and the valves are of acid-resisting type.

thus forms what is really the make-up of the preparation system. Settlings or sludge from this tank are cleaned out once a week.

The main supply pumps are two duplex units installed in the pump house, which is a two-story structure adjoining the breaker. Each machine consists of two single-stage centrifugals driven by a 200-hp. induction motor. These machines are under a constant suction head from the settling tank and discharge to the top of the breaker. Either machine will supply all the

**Fig. 9—Loading a Car Under the Breaker**

It takes only a few minutes to fill a car as the capacity of each coal pocket above is greater than that of a railroad car. There are only two loading tracks under the breaker so that no appreciable delay in loading can occur or trouble would result. Because of the ample capacity of the pockets, however, no difficulty of this kind is experienced.

water required for sprays and the like, leaving the other pump as a spare.

On the floor above are installed two 14,000-gal. per minute centrifugal pumps supplying circulating water to the jigs. These are single-stage machines either of which is of ample capacity to supply all needs, so that the other may be held as a spare. Inasmuch as the water is used over and over again all these pumps, as well as all the water lines throughout the breaker are made of cast iron so as to resist the action of acid.

In the early portion of this article mention was made of the extreme neatness and cleanliness of this plant. Most people think of coal as being something that is

dirty, something that will contaminate, something that will smudge whatever it touches. Perhaps this belief is justified. If it be true, however, the Baker breaker is verily the "exception that proves the rule," for many a painstaking and scrupulous housewife keeps her beloved parlor in no more spick-and-span, apple-pie order than that in which this breaker is habitually kept. Concrete floors, as well as all machinery, window frames and the like are carefully painted, and an attendant—he could hardly be called a janitor—makes periodic rounds with a dust cloth and an O-Cedar mop.

To one familiar with the breakers of former days, breakers, where, as Berton Braley put it,

"There is coal dust on the winders an'  
there's coal dust in the air,  
It's stickin' to the timbers an' it's  
settlin' everywhere,

**Fig. 10—Interior of Railway Scale House**

Railroad scales are installed both above and below the breaker. The "weighman"—who in this instance happens to be Miss Haggerty—is here shown recording the weight of a loaded car just before it is turned over to the railroad company for transportation to market.

**FIG. 11  
Circulating  
Pumps**

These machines are duplicates, either being capable of supplying the jigs with water. They are installed in the pump house which is separate from, yet attached to the breaker as a kind of a wing. Here, as in the breaker itself, note the extreme cleanliness—everything is neat, spick and span.

"It's clingin' to our eyelids an' our whiskers  
an' our hair

An' we eats it in the breaker by the pound!"  
this may appear like carrying neatness to an unnecessary extreme. This view, however, may be open to serious question.

#### THE UNCLEANLY BREAKER IS NOT PROFITABLE

As a matter of fact neither men nor machines can do their best when lungs are clogged with dust, bearings "stogged" with dirt and all movements are hampered and trammelled with this material. Certainly enough squalor and filth may be found in most mining communities to satisfy anyone who believes that dirt is the running mate, the unavoidable accompaniment of coal production.

On the other hand it is well-known that no single force available to the coal operator is more potent in its influence for good or evil, more conducive to success or failure as the case may be, than the morale of the personnel. Though it may be possible to foster and maintain a good morale in the organization under surroundings less æsthetic than those existing at Baker, the chances are strong that this desirable influence may be brought to its highest degree of perfection in surroundings of which a man well may be proud and for which he may acquire a real regard.

It is the exception rather than the rule that any human being can take genuine pride in, or exhibit a real affection for, anything or anybody that is unkempt. This is quite as true of localities, places and environments as it is of personalities.

Roper, general electrical foreman; (20) E. H. Adair, attorney.

*Hampton Power Plant and Distributing Towers*

## Glen Alden Generates and Distributes More Power Than Any Utility Firm in Hard-Coal Region

With Five Hundred Miles of Electrified Track, Many Breakers and Several Times as Much Water as Coal to Lift the Glen Alden Has Line Pressures as High as 66,000 Volts

BY EDGAR J. GEALY

Electrical Editor, *Coal Age*, New York, N. Y.

**A**LTHOUGH not the first anthracite mining company to use an electric mine locomotive, hoist or pump, the Glen Alden Coal Co. has for many years done most of the pioneering work in adapting electrical equipment to mine service. Today the company is recognized as having the most highly modernized and electrified coal property in the anthracite region. Present-day mining methods and many future developments in the industry will depend largely upon the past and present experiences and practices of this company's engineers.

Growing from a business which originally consisted of the purchase of a few lamps, telephones and signals the electrical purchases in this region for mine equipment have increased to about \$12,000,000 annually, to say nothing of the enormous volume of electric power-driven apparatus which always goes hand-in-hand with such development.

Economy, reliability, and safety were the impelling forces which have promoted this progress. The conditions to be met were adverse to the usual type of electrical apparatus. The liability to dangers and delays caused by acid mine water, coal dust, shock and vibration, all had to be considered. Nevertheless, the progress was consistently steady.

### UTILITY PLANTS IN REGION MAKE LESS CURRENT

Today the Glen Alden Coal Co. generates, distributes and uses more electrical energy than any individual public-utility company serving the northeastern section of Pennsylvania. Its power transmission lines extend from one colliery to another over a territory 24 miles

long. Line pressures as high as 66,000 volts are used. In and around Scranton the 250-volt direct-current distributing system of eight or nine different collieries forms a superpower network supplied from many scattered power-converting substations located on the surface and inside the mines.

The electrified track mileage of the fourteen collieries operated by the company totals about 500 miles. Four hundred and seventy-one trolley and storage-battery locomotives gather and haul approximately 10,000,000 long tons of coal per year.

The hoisting problems are many and varied. Some of the main hoisting shafts operate from two to eight different levels varying in depth from 20 to 1,400 ft. Inside the mines many large hoists are used on steeply pitching grades where from one- to ten-car trips are handled at speeds often greater than 1,200 ft. per minute. Room and car-haul hoists supplied either from low-voltage alternating-current lines or from the trolley system are scattered throughout the mines.

Anthracite mining companies as a whole pump about eleven tons of water per ton of coal mined, and the properties of the Glen Alden Coal Co. are no exception to this average. Most of the mines are located under or near the Lackawanna or Susquehanna Rivers, and in many places the coal beds are close to the surface or actually outcrop. These conditions require large pumping capacity.

Fortunately due to the nature of the coal beds, in the Scranton district, and also due to clever engineering and mining all the water from five and most of the water from three of the mines in this region is collected in a common sump. In this basin the company has built the largest pumping station in the coal fields. Five 5,000-gal. per minute centrifugal pumps each driven by a 1,000-hp. alternating-current motor are

NOTE—For years the surplus energy from the generating plant shown in the headpiece has been fed into the lines of the coal power company during emergencies. Direct connections to the large pumping station located nearby makes it possible to use a large amount of the power at low line losses. All the collieries in the Scranton district of the company receive power from this plant.

located in this pump room. On the surface nearby an 800-hp. automatically operated water hoist is held in reserve.

The ventilation problems are numerous and important, principally because of the many beds of coal mined from one shaft. The haulageways in some of the mines are long and irregular. Many of the roads and air-courses connect with adjacent mines and the properties of other companies. The mines near Nanticoke are some of the most gaseous in the world; consequently great care and consideration must be given to the ventilating system. At many of these mines auxiliary reserve fans are provided, some of which are operated by electric motors and some by steam.

#### MORE POWER USED ABOVE THAN BELOW GROUND

Modern coal preparation methods have necessitated many changes in the design of coal breakers and washeries. The use of large volumes of circulating water to prepare the coal has required numerous pumping units. Each process of breaking, screening, jigging, elevating and conveying the coal requires large amounts of power. Consequently, the power used to prepare the coal is often much greater than that to mine and transport it to the breaker.

In the Glen Alden breakers alternating-current inclosed-type motors generally are used. To provide positive safe operation and eliminate fire hazards motor-starting contactors and switching apparatus are located in separate control rooms near the breakers or in inclosed fireproof compartments built inside the breakers. Push buttons are located wherever it may be necessary to stop the motors in an emergency and all equipment may be started from points where the operator has full view of the apparatus being started. Usually the large induction-motor load of the breaker must be corrected for poor power factor and to accomplish this end synchronous motor-generator sets equipped with oversize motors wound for the same voltage as the

One of the Large Induction-Motor Hoists

This hoist room like many others is modernly equipped with automatic safety devices. Overspeed and overhoist protective features make accidents unlikely. The lighting fixtures are arranged so as to prevent glare. Extensive changes are contemplated when the company will electrify many of the present steam-operated hoists.

breaker motors are often used and located near the main breaker transformers.

The 60-cycle, three-phase power-generating system of the company consists of four separate power plants having an aggregate capacity of 31,000 kva. These plants are advantageously located so as to be near centers of loads, utilize exhaust steam, provide economic transmission, proper line voltage and continuity of service. The largest of these plants is located near Nanticoke on the bank of the Susquehanna River.

The next largest plant is known as the Hampton power house. This plant is located near the load center of the Scranton district and also near the mammoth Hampton pumping station.

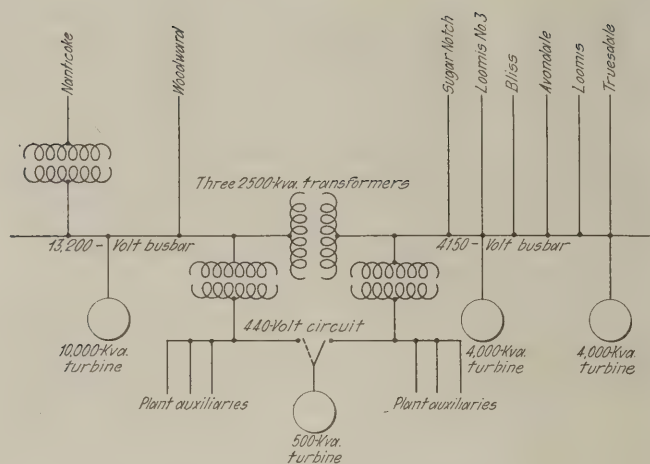

The third largest power plant is located at the extreme end of the properties. This plant, located at the Storrs colliery, furnishes power for the electrical equipment in its vicinity and thus obviates the neces-

Where High Voltages Are Reduced for Distribution to the Many Drives

These towers and transformer substations represent the latest practice of the company. They are built to stand as long as the breakers will operate. The supply lines to the newest breakers are all placed in underground conduits. All the other power lines are run on steel poles and towers around the outer limits of the colliery yard.

**Main Power Lines at Nanticoke Plant**

Separate lines direct from the power plant to the various collieries make it easy to sectionalize troubles. Interconnecting circuits between many of the mines provide means for balancing the distribution system.

sity for transmitting large quantities of power to this point from the Hampton power plant. The smallest power-generating station is at the Woodward colliery, near Kingston. This plant effects large savings by utilizing exhaust steam from the engine-driven shaft hoists and fans used at this colliery.

#### NANTICOKE PLANT USES RIVER FOR COOLING

The Nanticoke power plant was located near the Susquehanna River so as to obtain readily the necessary cooling water. This plant is one of the largest in the region and may be easily expanded to an almost unlimited generating capacity. At present the plant generates about 7,500,000 kw.-hr. per month. Additions which will cost over a million dollars are now being made and a 12,500-kva. turbo-generator will be installed.

The present equipment at this plant consists of one 10,000-kva., 13,200-volt turbo-generator, two 4,000-kva., 4,150-volt turbo-generators and one 500-kva., 440-volt turbo-generator.

All these machines are interconnected through transformers so that all of them are used to supply power to the transmission and distribution lines. Six oil switches control the same number of 4,150-volt distributing lines supplying the collieries in the immediate vicinity of the plant. Another oil switch controls a 13,200-volt line which ties the plant with the Woodward

power station. Still another oil switch controls the short 13,200-volt line leading to a bank of three 4,000-kva. water-cooled transformers which boost the pressure to 66,000 volts for the tie line to the Hampton power plant which is about 21 miles away.

Leaving the power house at Nanticoke this high-tension transmission line spans the Susquehanna River by means of steel towers. The line wires consist of No. 2 soft-drawn stranded copper conductors except at long spans, where 4-0 stranded copper conductors are used. Excepting at the long spans the line is on butt-treated wood poles. Between the Nanticoke and Hampton plants this line crosses the Susquehanna River at two places and for the greater part of the distance it runs near the top of the mountains on the west side of the valley. The insulators on this line have made a wonderful record. Ever since 1919 when the line was put in service there has been no shutdown due to an insulator failure.

Near the Hallstead colliery at Duryea a tap is taken from the transmission line to supply equipment located at this operation. Here provision has been made should occasion arise, to open the line and furnish power to the Hallstead colliery from either the Hampton or Nanticoke plant.

The Hampton power house uses mine water for cooling purposes. The tie line with the Nanticoke plant is connected to three 4,000-kva. water-cooled transformers, duplicates of the step-up transformers at Nanticoke. However, at the Hampton plant the low-voltage windings of these transformers are connected for 4,150 volts. The present equipment in the Hampton plant consists of one 5,000-kva., 4,150-volt turbo-generator and two 2,000-kva., 4,150-volt turbo-generators.

#### EMERGENCY CONNECTION WITH POWER COMPANY

Many 4,150-volt distributing lines radiate from this power house. Two of these lines are directly connected with the Scranton Electric Co. and only used in case of emergency. The others run to the various collieries nearby. Two 16,000-volt lines also run out of this plant. One connects with the Storrs power house, and the other feeds a long line which supplies the Diamond colliery and ultimately connects with the Scranton Electric Co. and the Keyser Valley shops of the Lackawanna R.R.

One 2,500-kva., 2,300-volt turbine at the Storrs colliery supplies part of the day load at this end of the

#### Typical Fan Drives

By installing duplicate fans like these the possibility of a shutdown at this mine is remote. Notice that the motors and drives are alike. This is another example of neat, permanent construction. The conduits and wiring fixtures are installed to last as long as any part of the machinery.

Interesting Views of the Nanticoke Power Plant

A—Outside view of boiler and generating plant. Here the small-size fuel is burned and the power transmitted over 24 miles. B—One of the large generating units. This machine has a full-load capacity of 10,000 kva. C—Where the power circuits are controlled. Continuity of service is of paramount importance; hence the rugged construction of these switches. D—Large turbine condenser and drive. The cooling water for this unit comes direct from the river where there is always an ample supply. E—How the plant is connected with other stations. The spans across the river are on steel poles. On the mountainside the line is run on butt-treated wood poles.

**Fan Drive with Anti-Friction Bearings**

When this installation was made, the workmen claimed that the large pulley was so well balanced and the frictional resistance was so low that a small nut placed on a spoke would cause the pulley to rotate. At the Loomis colliery near this installation mine gas accumulates rapidly. Consequently any savings in power in the fan drives are of great importance, for the fans must be run continuously at full speed.

line. The water used at this plant is mainly purchased from the water company. In spite of this drawback the demand for a power plant at this place became imperative when the new breaker was electrified and it became necessary to handle at this colliery most of the mine water of adjacent mines.

The transmission and distributing lines at the Storrs colliery are nearly all underground. Wherever it was necessary to run overhead wires they were carried on steel poles along the outside edges of the colliery yard. The underground conductors consist of lead-covered cables run in fiber duct concreted in troughs.

The Woodward power plant, installed in 1912, is an unusual installation. It consists of one 1,000-kva. low-pressure turbine. It utilizes the exhaust steam from three large steam-operated hoisting engines, three fans and one air compressor. The condensing water is circulated through a cooling tower which is assisted by a large air-circulating fan. Almost every year since it was installed this turbine has generated 1,800,000 kw.-hr.

The breaker at this colliery is completely electrified and for several years held the world's output record for anthracite, preparing over a million tons per year. At present the electrically operated Truesdale breaker of the same company holds the record, shipping about a million and a quarter tons of anthracite per year.

The boiler fuel used at the various boiler plants supplying steam to the electric generating equipment is what is known as buckwheat No. 4 or barley No. 2. This is a very fine grade of fuel which is unsalable on the market. Most of it comes from the fines on the ends of the various screens used in the breakers. Each boiler plant depends upon the collieries in its immediate vicinity for its supply of this fuel.

The present boiler equipment at the Nanticoke plant consists of twenty standard two-drum, 303-hp. boilers each equipped with a traveling chain-grate stoker. About 14,200 long tons of fuel are burned per month and 146,000,000 lb. of water evaporated in the same period. A large part of this steam is used to generate

electric power used for pumping purposes. Large pumps at the plant supply water to several of the collieries located within a radius of 3 miles from the plant.

Ordinarily the boiler-feed water is raised to a temperature of from 200 to 208 deg. The volume of cooling water depending on the load carried by the plant, the vacuum maintained, and the temperature of the water as it comes from the river. The steam pressure supplied by the boilers is about 160 lb., and the vacuum at the turbines varies between 28 and 29 in.

#### LARGE PUMPING UNITS GIVE GOOD LOAD FACTOR

The peak load comes on the plant soon after eight o'clock in the morning. However the day load from 7 a.m. to 3 p.m. is quite steady. Because of the demand made by the big pumps provided where large quantities of water must be raised to the surface much of the pumping is done at night. This makes it possible to operate the generating plants at good load factors.

About a year and a half ago a large dam across the river below the Nanticoke power plant broke. Since that time the elevation of the water at the penstock is much lower and during the dry seasons, although there is ample water in the river, it is necessary to locate a pump on the bank of the stream close to the water. This pump is mounted on a truck and lowered down a plane. During normal operation 11,000 gal. per minute are required for the two surface condensers on the two 4,000-kva. turbines and a further 10,000 gal. per minute for a jet condenser on the 10,000-kva. turbine.

The Hampton boiler house furnishes large quantities of steam for use at the many collieries nearby, consequently the boiler capacity is much greater than that required to operate the turbines in the power house. In the boiler house there are fifteen 313-hp. boilers, five 613-hp. two-drum hand-fired boilers and three 613-hp. double-drum boilers fired by three double-compartment stokers. These boilers operate at about 148-lb. steam pressure, use 14,500 long tons of fuel per month and evaporate 151,022,000 lb. of water in the same period. The average monthly power output of the generators is about 3,420,000 kw.-hr. Because it

**Portable Gathering Mine Pump**

Units like this concentrate the water into large sumps where it is handled by centrifugal pumps. As the mining progresses these pumps are moved to new areas. Frequently they receive power from the trolley system. In the old workings where mining is scattered over large areas, many of these pumps are required to keep the rooms from filling up with water.

#### An Unusual Power-Generating Station at the Mines

Located where it can use what was formerly waste steam this plant has for many years supplied 1,000 kva. into the company's power system. This station utilizes low-pressure exhaust steam from the hoisting engines and fans at the Woodward colliery. This colliery is one of the largest producers in the anthracite field, and it is therefore important that ample power be available at all times.

is necessary to use mine water for cooling purposes all the condensers, spray plates, cones and pipes are heavily wood-lined.

Ten 300-hp. hand-fired boilers supply the steam requirements at the Storrs boiler plant. These boilers supply 140-lb. steam pressure for the turbine, fans and hoisting operations. The cooling water is circulated from the condensers to a large spray pond adjacent to the power house.

The steam used at the Woodward power house was formerly wasted. This plant uses exhaust steam at 3-lb. pressure from the colliery steam engines. The condensing water is pumped into a cooling tower and circulated back to the condenser. This method of cooling is very successful at this plant because of its relatively small capacity and low steam pressure.

#### MOTOR-GENERATORS REPLACE ROTARY CONVERTERS

Years ago when the only electric power load at the mines consisted of locomotives and a few direct-current pumps and hoists, most of the power-converting units were rotary converters. Now when many of the old breakers have been abandoned and new ones electrically equipped with induction motors have taken their places, there is a greater need for power-factor corrective equipment. Large pump and hoist motors have increased this need, consequently, many of the later power-converting units are motor-generator sets. Some of the motors on these units have been purposely made larger than ordinarily required so as to be able to correct the lagging power factor of the large induction-motor loads in the breakers and washeries.

In some places the converting substation is located outside the mines near the breaker, and the synchronous motor on the motor-generator set is wound for the same voltage as the breaker motors. This permits power-factor correction on the load side of the transformers thus effecting power savings and eliminating the necessity for over-sized transformers.

Nearly all of the power converting substations are located adjacent to or near a hoist, pump or fanhouse, therefore, the company has not considered it particularly necessary as yet to provide complete automatic operation. The direct-current system of most mines is protected by means of automatic circuit breakers which in some cases are provided with the self-reclosing feature. Where the machines operate in parallel with other units or are tied into a direct-current distributing system they are protected against reverse-current and overspeed.

#### How the Direct-Current Feeders Are Protected

These circuit breakers not only open under overload but sectionalize faulty equipment and grounded supply circuits. In the substations slightly different breakers make the direct-current distribution system function automatically. The attendant need only oil the generating equipment and see that the alternating-current apparatus functions properly.

### Storrs' Mine Pumps

The water at this colliery contains much acid, yet these pumps have given great satisfaction. Large 1,000-hp. motors, duplicates of those driving the Hampton pumps are supplied with energy direct from the local power plant. In emergencies and also at nights these pumps may also draw power over the tie line connecting the Storrs' power plant with the Hampton power house.

At most of the stations it is merely necessary for the operator to start and stop the machine and oil it occasionally, all other normal conditions are handled by the station protective equipment.

To the 471 trolley and battery locomotives now in service 26 new locomotives recently have been added. Those now in service consist of seventy-one 6½ ton, one hundred 7-ton, one hundred and ninety-three 8-ton, thirty-nine 10-ton, thirty-nine 13-ton, three 15-ton, one 20-ton, two 26-ton trolley types and twenty-three storage-battery locomotives. Seventy-two of these locomotives including the two 26-ton units are in service at the Truesdale colliery. As in the mines of many other anthracite companies the tracks in the Glen Alden mines are very irregular. Much of this is due to former methods of mining and to the large quantity of second mining being done. For these reasons the track-bonding, trolley and feeder systems in many sections of the mines are not very modern. However, main haulageways and main feeders are now being remodeled along more approved lines.

Most of the main shaft hoists are steam driven, although several large induction motor-driven hoists have

lately been installed. One of these new hoists at the Loomis colliery is driven by a 600-hp. motor and controlled by a liquid rheostat, another at the No. 3 Shaft of the same colliery is driven by a 350-hp. induction motor. Both of these hoists and several others are fully equipped with automatic safety devices including, overspeed, overwind and overload protective features.

Some of the pump installations of the company are the largest and most up-to-date in the region. By the autumn of this year none of the pumps in the mines will be operated by steam or air. At present 301 centrifugal pumps are in operation to which are connected 39,000 motor horsepower and over 2,000 steam-engine horsepower. The aggregate capacity of these pumps is approximately 500,000 gal. per minute. There are also 239 motor-driven plunger pumps driven by about 3,500 motor horsepower. These pumps have a capacity of 28,000 gal. per minute. The combined motor horsepower of these two classes of pumps is about 42,500 and the combined pumping capacity approximately 528,000 gal. per minute. The total number of pumps including hand-operated and jig pumps is approximately 998.

### Tandem Unit

It seems quite natural that large tandem locomotives should be found at the Truesdale Colliery, the giant operation of the anthracite region. One of these double units hauls coal over the surface from the Sugar Notch opening to the breaker. Nearly all the trolley locomotives of this company operate from 275-volt circuits.

**Hampton Pumping Station, Largest in Region**

One of five 5,000-gal. per minute centrifugal pumps which raise the water 599 ft. to the surface. At this pumping plant all the water of five mines and most from three mines is gathered and pumped to a large reservoir. Each of these pumps is operated by a 1,000-hp., 2,200-volt, wound-rotor type induction motor.

Each of the five 5,000 gal. per minute pumps located at the Hampton pumping station, previously mentioned, pump against a 500-ft. head. During dry seasons 8,000,000 gal. of water are pumped in 24 hours and in the wet season 20,000,000 gal. are raised to the surface in the same length of time. The weight of bronze alone in each of these pumps is approximately 17,000 lb. The pumps are primed by air ejectors or vacuum pumps. Five 300,000-cm. three-conductor, varnished-cambric, lead-covered, armored cables, suspended in two lined boreholes, deliver 2,300-volt energy to the 1,000-hp. motors connected to each pump. Two of the pumps are controlled by automatic starters and three by non-automatic control panels.

At the Cayuga mines is an automatic pumping station. Originally a manually operated 1,500-gal. 630-ft.

head centrifugal pump replaced a large steam-driven reciprocating unit. In September, 1923, additional control equipment was added to the new centrifugal pump, so that now it is automatically primed, started, stopped, controlled and protected. When the water in the sump rises to a predetermined level the pump is automatically primed and started. While in operation it is protected against overload, loss of water, air leaks and column-line breaks. When the sump has been emptied to a predetermined level a float operates the control devices and automatically stops the pump and everything is made ready for a complete restart whenever the water again rises to the starting level. This pump is driven by a 400-hp. 440-volt induction motor.

#### ONLY A FEW SIZES OF CENTRIFUGAL PUMPS USED

By standardizing upon a few different sizes of centrifugal pumps many of the ordinary pumping problems have been obviated. This makes it relatively simple and inexpensive to carry in stock repair parts for nearly all the important pumps. Whenever an unusual accident occurs it is a simple matter to take an impeller, bearing or casing from one mine to another to make a hasty repair.

The large centrifugal pumps are standardized into three units. The first is a 12-in. three-stage unit having a nominal rating of 4,500 gal. per minute against a 300-ft. head. This pump is used between limits of 5,000 gal. per minute at 250-ft. head and 4,000 gal. per minute at 350-ft. head. The second unit is an 8-in. two-stage volute pump having a nominal rating of 2,000 gal. per minute against a 200-ft. head. This unit is used between limits of 1,400 gal. per minute at 230-ft. head and 2,400 gal. per minute against a 150-ft. head. The other large unit is a double suction single-stage volute pump nominally rated 3,500 gal. per minute against a 100-ft. head and is used between limits of 2,800 gal. per minute at 140-ft. head and 4,000 gal. per minute at 70-ft. head.

#### TEN-STAGE CENTRIFUGAL LIFTS WATER 920 FT.

The largest capacity pumps at the Glen Alden's mines are two located in the Baker breaker for circulating water to the jigs and screens. Each of these pumps has a capacity of 14,000 gal. per minute. The highest lift of any of the centrifugal pumps on the Glen Alden property is on a 6-in. ten-stage, 800 gal. per minute

#### Pumproom Interior

Automatic pumping station at Cayuga. This centrifugal pump replaced a steam-driven unit. Centrifugal pumps save much pump-room space aside from their many other advantages. At this station the pump starts and stops when the water in the sump rises or is lowered to predetermined levels. At the extreme left of the picture is a part of the old pump foundation and the new vacuum pump which primes the centrifugal unit. Note the bearing thermostat on the motor.

### Repair Shop

Large and small motors and other electric equipment can be repaired in this shop. Standard and special coils are made on modern coil-winding machines. Each motor armature is wound, baked and machined before being placed in service. Spare coils and commutators are always kept on hand. Even large converter rotors are quickly repaired and returned to the mines by the auto trucks of the electric department.

unit at the Truesdale mines. This unit pumps against a 920 ft. head.

All the bronze centrifugal pumps purchased by the company are bought upon standardized specifications. The important specifications for a typical two-stage pump are in general as follows: The pump is to operate at a full-load speed of 1,170 r.p.m.; it is to be of the balanced piston multi-stage centrifugal type, preferably without diffusers; consideration will be given to two-

stage back-to-back type pumps having volute casings; preference will be given to pumps which can be most readily opened for inspection or repairs; casings to be of acid-resisting bronze and sufficiently heavy to withstand a working pressure equal to twice the rated head; impellers to be of the inclosed type and to be of bronze; all parts of the pump coming in contact with water to be of bronze consisting of 75 per cent copper, 10 per cent tin and 15 per cent lead.

## The Miner's Torch

### The Closed Door

**O**CCASIONALLY we find men who are rated as conspicuous successes in their line of endeavor who are willing to talk about the things to which they give credit for their success. Whether such talks have any real value to the fellows who are trying to climb higher on the ladder of success is a fit subject for debate, but when we consider that two American monthly magazines are filled almost entirely with literature of that kind, and considering further that one of these magazines has almost the largest circulation of any monthly in America we must admit that such literature undoubtedly has wide appeal.

Recently I was thrown with one of the most successful designing engineers of America (a man who has clients in a number of states and who has accumulated a no inconsiderable fortune from his professional activities) and in the course of our conversation he grew reminiscent and told me some things about himself and his methods that were not only interesting but suggestive as well. Had a professional interviewer been present my friend would have had a difficult time keeping his picture out of the magazines. This man attributes most of his success as an engineer to assistance received from sales engineers.

Here is the way he expressed it, as near as I can repeat it: "The best posted men in America today are the sales engineers who are in the employ of the large

manufacturing companies. They not only know all about all of the things which their employers manufacture but they are just as well posted about the things manufactured and sold by their competitors. Furthermore, they are widely traveled as a rule and have seen their equipment in operation in all parts of the country under widely varying conditions and for every conceivable purpose. A machine or method may succeed in one part of the country and fail in another; if there is a reason they can tell you why. If there is no reason they can put you to thinking. And generally they are about as honest as the average humans.

"Numbers of times I have had my mind made up and was ready to recommend equipment for special jobs only to have my reputation saved at the last moment by a word of advice from a sales engineer who easily convinced me that my judgment was poor.

"And here is the strange part of the whole thing to me; the very fellows who are most in need of the kind of advice that sales engineers can give, absolutely refuse to give them an audience, even going so far as to insult them if they cannot get rid of them in any other way. Why there are some engineers who feel so strongly on the subject that they go all to pieces at the very mention of the title "Sales Engineer." If a man unfortunate enough to possess a card bearing that title following his name should use his card for purposes of introduction with engineers of that type he should count himself lucky if he escaped from the office without being offered personal violence."

**HYDROGEN HAS BEEN SOLIDIFIED** by Dr. C. W. Kanolt. The gas was subjected to a pressure of 3,000 lb. per square inch, cooled artificially to -425 deg. Fahr. and further cooled 14 deg. Fahr. by evaporation.

## News Of the Industry

### Coal Operators Rejoice at Nomination of John W. Davis for President

Industry Feels Assured Against Advocacy of Regulation—Mining Unlikely to Be Prominent in Campaign—Charge of Wall Street Domination Disproved by Defense of Glass Blowers' Union

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Regardless of party affiliation, the coal operators are rejoicing in the selection of John W. Davis as the presidential nominee of the Democratic Party. With the party's leadership in his hands the industry feels assured that no unsound foray into the regulation of the coal industry will be advocated during the campaign by the Democrats or put forward by the party if it be vested with the administration of the government.

Had one of demagogic tendencies been selected as the Democratic standard bearer the regulation of the coal industry easily could have been made one of the major talking points. There would have been the further temptation to do it because it is known that Senator La Follette will make it one of his principal issues. While the Democratic platform mentions by name only the anthracite industry, it is a fact that the original draft of the plank applied to the entire coal industry. The point was raised in the resolutions committee that there is nothing in the bituminous-coal industry which possesses a semblance of monopoly.

#### New England Hits at Anthracite

Since it was really anthracite at which the New England members of the committee were striking, there was no objection to confining the specific mention to that type of coal.

With Mr. Davis as the Democratic candidate, the probabilities are that little will be heard of the anthracite regulation plank. To start with, Mr. Davis comes from a coal-producing state. He is particularly familiar with the bituminous-coal industry and understands the situation in the anthracite region. He knows that it is going to take more than coal to cause the strongly Republican states of New England to abandon their favorite son. The probabilities are that under Mr. Davis' leadership no particular bid is going to be made for the New England vote. He knows that energy can be expended in other states where the prospect of carrying them is better. Moreover, Mr. Davis knows that any proposal to regulate the anthracite industry will be regarded by the bitu-

minous-coal industry as the first step toward the regulation of the latter.

Mr. Davis also knows that it is impossible to regulate profits without regulating prices, and that you cannot regulate prices without eventually regulating wages. He knows just how

©Harris & Ewing

John W. Davis

Nominated for President at the Democratic convention in New York City, July 10, on the 103d ballot.

unpopular any such program would be with capital and with labor. Labor might go along on a proposal to nationalize coal mining—although it is divided on that—but it never would seriously recommend that the government undertake the regulation of this speculative and highly complicated industry.

From the standpoint of practical politics it seems improbable that a leader of Mr. Davis' understanding would give emphasis in the campaign to a recommendation which would be overwhelmingly unpopular in the coal-producing states, several of which are of doubtful political complexion. Any proposal to regulate the coal industry from a federal bureau in Washington would be overwhelmingly disapproved in such states as Illinois, Indiana, Kentucky and West Virginia.

The main weakness of Mr. Davis as a candidate, it is asserted, is that he appeals strongly to Republicans but will not get their votes. William Jennings Bryan had much to say at the New York convention about the impossibility of Mr. Davis freeing himself from his allegiance to Wall Street. Big interests have contributed so much to his income that Mr. Bryan, prior to the nomination of his brother as Mr. Davis' running mate, was certain that they would continue to be his master. In that connection, however, it is pointed out that there will be difficulty in convincing the country that Mr. Davis is a creature of Wall Street, since it was he who drafted the Clayton Act, who has more than any other one man, some claim, to establishing the principle that labor is not a commodity and who has been retained by trade unions as frequently as he has been by big business.

The last case he won before the Supreme Court of the United States was for the glass blowers' union, a case involving alleged violations of the anti-trust statutes by the union.

#### Mine Workers Opposed Davis

At the convention the chief opposition to Mr. Davis' candidacy appeared to come from the United Mine Workers. The United Mine Workers' only argument against him, so far as it could be learned, consisted in the fact that he had represented the Bituminous Operators' Special Committee before the Harding Coal Commission. As in the case with Mr. Bryan, there was no charge that Mr. Davis had made any misrepresentations in his service for the coal operators. The opposition seemed to be based solely on the ground that he had committed the unpardonable crime of having accepted employment at their hands. While Mr. Davis did appear before the Coal Commission in behalf of the Bituminous Operators' Special Committee, his participation was limited to legal questions with which the United Mine Workers probably would take no issue.

#### Ford Leases Superior Dock

William S. Harmon and Frank L. Stein, receivers for the Maynard Coal Co., of Columbus, have closed a lease with the provision of purchase for the properties of the Superior Coal & Dock Co. at Superior, Minn., to the Ford Motor Co. The deal has been pending for some time and the approval of the court was given July 12. The lease carries with it the privilege of purchase within a year at the announced price of \$650,000 and accrued taxes of \$8,500. The Ford Motor Co. will take possession of the dock at once.

## No Early Change Likely in Rules for Mine Rating and Car Distribution

No changes in the rules governing the ratings of coal mines and the distribution of cars to these mines seems probable at this time. It is confidently predicted by those who oppose any change in the present rules that the Interstate Commerce Commission will give the existing rules a thorough trial before ordering any change. The questions asked by members of the commission indicate that there is little disposition to put into effect the recommendation in this regard of the Harding Coal Commission.

The National Coal Association in opposing any change, urging that present rules be continued until there has been experience with them under car shortage conditions. In fact the association took the ground that the commission does not have the authority to promulgate an order placing mines on a commercial basis until there is a finding that the present rules are in violation of the statute. The National Coal Association believes that the commercial basis would produce discrimination between seasonal and non-seasonal mines and between large and small operators, and would place in the hands of the carriers an implement which could be used most insidiously were they inclined to discriminate. Issue also is taken with the claim that the proposed rules would eliminate the economically unnecessary mine or that they would simplify railroad operations.

### Gutheim Presents Case

On behalf of the Pittsburgh Coal Producers' Association, August G. Gutheim contended before the commission that "the rating of bituminous-coal mines for car-distribution purposes, based wholly or in part upon the commercial ability of such mines to sell coal the year round, would be unjust, unreasonable and would discriminate unlawfully against coal operators and against the railroads."

Some of the contentions set forth by the Bethlehem Steel Corporation follow: "Bethlehem operates seven large steel plants with a coal requirement at full

operation of about 12,000,000 tons annually. It owns 31 coal mines, operating 25 tipples, with an annual capacity of about 10,000,000 tons. Practically speaking, Bethlehem is a self-contained industry as to its fuel supply.

"When Bethlehem's steel plants are running full, they take all the coal its mines can produce. The steel business is subject to sharp fluctuations. At the present time Bethlehem's plants are operating at 40 per cent of capacity. Under these conditions, which are recurring and not unique, Bethlehem's mines have a potential production of 6,000,000 tons which its plants do not need. It is Bethlehem's established policy not to mine and ship this coal but to confine the operation of its mines to the current needs of its steel plants. Operating its mines in this way, and using its 4,000 private cars to move its own coal, as needed, Bethlehem has obtained a satisfactory supply of the special fuel it needs, without becoming a disturbing factor in either the commercial coal market or the distribution of system cars. Its private cars have been sufficient to serve fully its mines and these mines have made no call on system cars in times of car shortage.

### Waste in Commercial Rating

"If Bethlehem were forced by the adoption of the proposed commercial rating rule to enter the commercial coal market with its 6,000,000 tons of unneeded production, the result would be waste and financial loss to Bethlehem and an aggravated depression to the commercial coal industry, already suffering from slack demand and overdevelopment.

"Bethlehem's study of the question of mine ratings in this proceeding has confirmed its earnest conviction that for the best interests of all concerned an industry owning its own coal mines and consuming their entire output should be permitted the use of private coal cars for that purpose. Thus and thus alone, can such in industry withdraw alike from the competition of the commercial coal market and the competition for system cars."

## Besson Must Pass Test, Court Decides

Leon Besson, Governor Davis' new head of the Kansas mine inspection department, succeeding James Sherwood, must pass that qualifying examination after all. The State Supreme Court has decided it. When he was appointed and the appointment was ratified by Governor Davis' two appointees on the Kansas Industrial Court, the third member, Presiding Judge John H. Crawford, protested that he was being railroaded into office and should be required to pass the examination for "deputy mine inspectors," a phrase used in the law covering the matter. Governor Davis and Besson contended that Besson was appointed as "state mine inspector" and therefore the law did not apply.

Two days following the ouster decision Presiding Judge Crawford announced that he and Judge Martin had appointed Ernest Shaw, chief deputy, to act as inspector. Besson continued at his office. He said he would do so until he received an official order from the Industrial Court to vacate it.

## K. U. Meguire to Open Big Strip Pit in West Kentucky

The Dawson Daylight Coal Co., in the Dawson Springs district of western Kentucky, which is controlled by K. U. Meguire and associates, of Louisville, is getting ready to launch what may be the largest coal stripping operation in the State of Kentucky. A branch line of the Illinois Central R.R. to this property was more than a year late in finally connecting it with the outside world, but the company, while handicapped in the matter of getting material and equipment to the property, has made headway and completed a tippie with a capacity of 5,000 tons of coal daily, or about 100 cars, before the railroad reached the property. At the present time the company is assembling a Bucyrus No. 320 revolving steam shovel with a 7-yd. bucket, which will be used for removing overburden.

This will represent the first invasion of the Meguire interests into the west Kentucky coal fields, the company having heretofore operated in eastern Kentucky exclusively, with some big plants in both the Harlan and Hazard fields.

## Electric Lamps Now in Use In Oklahoma Mines

The chief mine inspector of Oklahoma is losing his fight against the use of electric cap lamps in the coal mines of that state. The District Court at Oklahoma City has restrained him from preventing the use of such lamps and about 900 men wearing them have gone back to work in the three mines of the Rock Island Coal Mining Co. at Hartshorn. Inspector Ed Boyle has appealed to the Supreme Court of the state, but the lamps are in use and the company is producing coal once more after a shutdown lasting more than six weeks, during which the whole region has been upset by the violence of the argument over lamps.

The controversy has been brewing for two years, or ever since the Rock Island company put electric cap lamps into its No. 12 mine. A year ago when a district inspector ordered them into the company's other two mines with the company's entire consent, the chief inspector objected strenuously.

After John L. Lewis, president of the United Mine Workers, had helped write an electric-lamp provision into the wage agreement for the Southwest district early in May and the Rock Island company bought lamps for its whole group of mines and started their use, Chief Inspector Boyle went on a rampage, ordering the use of nothing but carbide lamps in Oklahoma and posting notices at the Rock Island mines threatening arrest for anybody who wore them and court action against any company that tried to use them.

This produced a strike at the Rock Island mines, fostered by an Alexander Howat element which is in control of the district union. Many mass meetings and much uproar followed before the mines reopened early this month under court protection.

### Boyle "Knocks" Electric Lamps

In spite of the claim of the company and of Bureau of Mines engineers that electric cap lamps are safest in gas, Chief Inspector Boyle contends they are dangerous. In a public statement he set forth his case thus:

"With an open-flame lamp the miner can tell by the flame the condition of the atmosphere. When conditions are dangerous, the flame is straight and does not quiver. He knows there is danger.

"The closed lamp gives less than 1 candlepower; the open flame lamp gives 5 candlepower. If you were digging coal in the bowels of the earth, which would you prefer? The Rock Island Coal Co. has used open-flame lamps down there for twenty years with the best of results. Why quit? Oh, just to save a few dollars. The lives of the men are worth saving too. That is what this department is for.

"Ninety per cent of the accidents in mines in this state are caused by other than gas explosions. L. C. Ilsley, engineer of the Bureau of Mines, Washington, D. C., testifying before the congressional committee after the Virginia mine explosion said: "The explosion was caused by an unapproved

C. W. Bryan

Governor Bryan established 158 coal stations in Nebraska and claims to have saved consumers \$10,000,000 in their coal bills.

electric coal drill; that in Pennsylvania by an unapproved electric coal cutting machine; that in Utah by an unapproved flame safety lamp."

"The idea is that the closed lamp without proper electric insulation throughout the mines is very dangerous because of fire flashes."

## Court of Appeals Affirms Decision Against Company In Coronado Coal Case

A decision of the Eighth Circuit Court of Appeals, filed at St. Louis, July 12, affirms the unanimous ruling against the Coronado Coal Co. made by the U. S. Supreme Court, June 5, 1922. The opinion was written by Judge William S. Kenyon and concurred in by Judges Walter H. H. Sanborn and Robert E. Lewis. This apparently brings to an end the ten years of litigation in which the Coronado company vainly sought to recover treble damages, amounting to \$600,000, from the United Mine Workers for destruction of property by striking miners at the Bache-Denman mines in Arkansas in 1914.

The case had been remanded by the Supreme Court in 1922 for a new trial after a lower court had given judgment to the Coronado company for \$200,000 damages, which would have been trebled under the Sherman anti-trust act.

On the ground that there was nothing in the evidence to show that the International union or International board of the United Mine Workers had authorized the strike or taken any part in preparation for it or in its maintenance or had ratified it by paying any of the expenses, the Supreme Court concluded that the International union and its officers should not have been held by the trial court as subject to joint liability with the district and local organizations and officers for participation in the conspiracy or for the destruction of property incident to the strike.

## C. W. Bryan, Nominee for Vice-President, Sold Coal To Consumers in Nebraska

On his arrival at Atlantic City, July 11, C. W. Bryan, Democratic nominee for Vice-President, said of his administration as Governor of Nebraska and his attitude on state ownership:

"We have reduced the price of coal of all kinds from \$3 to \$5 a ton. I furnished coal to municipalities and homes at wholesale. I have been selling it, personally, to 158 towns and cities in Nebraska, buying it in carload lots from the mines. This forced the coal combination to reduce its prices. The people saved \$10,000,000 last year by our coal stand. I am not in favor of federal, state or municipal ownership of anything except natural resources, such as water, but when business combinations, particularly utilities and those supplying vitally necessary products, defy all authority and endeavor to mulct the public, then I think that the government should sternly repress them, using whatever means may be efficient."

Mr. Bryan pursued the same tactics with regard to gasoline and claims that he reduced the price in the capital from 23c. to 17c. per gallon. He proposes to do the same in all sections of the state unless the price is reduced to 15c. He claims to have reduced the cost of road building 25 per cent and the cost of gravel 33 per cent.

## Mines Bureau Plans Further Co-operation with British

In addition to interchange of the results of previous research work on safety in mining by the United States and British governments a technical representative of the British government will be assigned to the Pittsburgh station of the Bureau of Mines, while a member of the bureau's technical staff will be accorded similar facilities to observe the progress of British work, said H. Foster Bain, Director of the U. S. Bureau of Mines, on his return from the Empire Mining and Metallurgical Congress in London. The bureau is to undertake tests of the British "permitted" explosives. The British have been less successful than has this country in producing explosives that will give satisfactory service in coal mines.

A. C. Fieldner, superintendent of the Pittsburgh experiment station, with a member of his technical staff, now is in England conferring with the Fuel Research Board of Great Britain relative to the processing and better use of coal. This is in anticipation of the time when it will be necessary to supplement petroleum supplies with benzol and other oils derived from the by-products of the distillation of coal. Every effort will be made to avoid duplication of effort in research work.

Mr. Bain spent much time with Mines Minister Shinwell, and it is entirely probable that co-operation between the two governments will be much broader than is outlined in the actual agreement, which is limited to matters pertaining to safety.

## MacDonald, Ousted by Union And Reds, Seeks a Job

Duncan MacDonald, who for a few days was Presidential nominee of the Communist-controlled convention of the Farmer-Labor party at St. Paul, is now seeking any kind of job he can find.

For years MacDonald has been in the limelight in labor affairs in Illinois. He was secretary of the state coal miners' union and president of the Illinois Federation of Labor. But today he is out in the cold.

MacDonald's first clash in organized labor was with Frank Farrington, president of the Illinois Coal Miners' Union. As secretary of that organization MacDonald launched an attack on a series of alleged irregularities in Farrington's office. In the bitter fight that followed, MacDonald was ousted, but he was elected head of the State Federation of Labor through the votes of the coal miners. He met defeat at the next election, however.

At the recent Peoria convention of the Illinois miners' union MacDonald was mentioned as Farrington's probable successor. The miners wanted him to make the race, but advised him to follow a cautious policy. But with apparent success in sight MacDonald joined William Z. Foster and his cohorts in forming a new third party in the state, believing it afforded him the necessary weapon to continue his fight against the Farrington machine.

At the St. Paul convention MacDonald was nominated for President, but last Thursday he was supplanted on the ticket by William Z. Foster. The Muscovite label attached to the St. Paul convention didn't appeal to either the farmers or industrial workers, however, and they indorsed La Follette.

## Machine Loader Scale Is Signed in Illinois; Men to Get \$10.07 a Day

*Special Dispatch to Coal Age*

Chicago, Ill., July 15—A scale for machine-loader operators has been signed in Illinois at last. The Chicago, Wilmington & Franklin Coal Co. has agreed to pay its loader men \$10.07 a day beginning July 16 and during the remaining life of the Jacksonville agreement, to which Illinois is committed.

This scale is not statewide because no other companies have loading machines, but now that a wage rate has finally been fixed, that rate naturally will be the one adopted by any other companies that go in for machine loading. In the agreement it is covenanted that the men are to work under the direct supervision of the company a full eight hours a day, and that in case of machine breakdown they are to perform any sort of labor that may be assigned them. It is "recommended" that they be given hand loading in such cases.

The union agreed to a day wage instead of a tonnage basis of pay because it is evident that the use of loading machines is still in an experimental stage. The scale is to apply to all loader operators, no matter what the developments of loading may be during the life of the agreement. The new scale was fixed at \$10.07 a day largely because that is the rate in Indiana, where a number of loaders are at work. Up to July 16 all the men operating the 14 Joys and the four Myers-Whaley loaders in the Orient No. 2 mine of the company were on development work and received \$8.54 a day and yardage. Under the agreement men on drilling and snubbing get \$8.04 a day. Cutting machine runners receive the union scale of 13c. a ton.

## Six Kanawha Companies Now Working Under New Scale

Of the twenty-six companies which joined in posting a new wage scale in the Kanawha region of West Virginia, marking a formal severance of relations with the United Mine Workers, six companies were able to resume operations July 7, under the new scale, according to reports made to the Kanawha Operators Association. The employees were glad to go to work again after an idleness lasting since April 1. The twenty-six companies referred to operate 45 mines in the Kanawha region and up until April 1 operated in agreement with the union.

A number of other companies in the Kanawha field have been operating on a non-union basis since the strike of 1922. The group of operators who have just announced their determination to operate on a non-union basis were unable to compete with the non-union mines when the union demanded that the Jacksonville agreement be subscribed to and hence shut down their mines until such a time as their employees would indicate that they were willing to accept a reduction in order that operations might be resumed. Action taken by the group of 26 operators means that the Kanawha field, formerly a union stronghold, is now almost exclusively non-union.

## Receiver Named for Egyptian And O. K. Companies

C. B. Thomas, referee in bankruptcy, East St. Louis, Ill., on July 11, was appointed by Federal Judge English as receiver for the Egyptian Coal & Mining Co. on the application of J. C. Hamilton & Co. of Marissa, Ill., and the Security National Bank of East St. Louis. The Marissa company holds the company's bonds while the bank is trustee under the bond issue.

The action was taken under a petition to foreclose the mortgage securing the bonds, which were issued in November, 1922, in the sum of \$250,000. The proceeds of the bond issue were used to improve the company's properties and to lease the O.K. Coal Co. property adjoining. J. A. Hamilton is president and W. E. Meek, vice-president of both companies.

Under the terms of the mortgage the trustee was entitled to foreclose if the mines were closed down and the bonds and interest not paid. Attorneys for the company admitted this condition and agreed to the appointment of Thomas as receiver. The company has assets estimated at \$450,000.

Last week stockholders of the O.K. company filed suit for a receivership, but this action was withdrawn preliminary to the Egyptian suit.

## "Soo" Shipments Gaining

Shipments of bituminous coal to the Northwest via the "Soo" Canals during June, according to the U. S. Engineers' office, totaled 1,493,759 net tons, compared with 1,138,398 tons during May. Anthracite shipments during June amounted to 205,342 net tons, compared with 61,084 tons during May.

## High Wage Rate of Teamsters Raises Retail Prices

In the accompanying chart is shown how the increase in the wages of wharfmen and teamsters has exceeded in Boston even the increases in the wages of the building trades. Whereas the building wage rates have risen about 70 per cent the wharfmen and team-

sters have been forced up 115 per cent. This probably is typical of the general condition. It will be noted that the wharfmen and teamsters, though their wage increases have been large, are not even now getting startlingly high wages. These wage-rate increases, whether justified or not, account in a degree for the high cost of coal at retail.

Comparison of Wages to Wharfmen and Teamsters with Cost of Living and Wages Paid in Building Trades in Boston, Mass.

Above the heavy line representing the wages paid to wharfmen and teamsters is placed the hourly wage paid between 1911 and 1924. To this is appended after 1913 the comparative rate per cent that any one wage rate bears to that ruling in 1914.

## Practical Pointers For Electrical And Mechanical Men

### Where Combination Locomotive at Mine Meets Unusual Conditions

A mining engineer recently presented an interesting haulage problem that can be solved practically in only one way. The conditions at his mine were such that coal cars from an opening near the tipple had to be transported over a short stretch of the railroad track before they could be unloaded. It was impossible to lay a mine track parallel to the railroad because a large building was on one side and a creek on the other. It was therefore necessary to use one rail of the railroad track and place another to suit the gage of the mine cars. When this was done another problem presented itself.

The haulage locomotive selected for this service was of the trolley type and therefore it was necessary to provide a trolley circuit where the locomotive was to travel. To meet the railroad rules it was impossible to install the trolley wire near enough to the railroad track to permit the use of a trolley pole of reasonable size. Hence the ordinary trolley locomotive would not meet the conditions.

A combination trolley and battery locomotive was suggested. When the locomotive would operate over the railroad track the battery power would be used but when the locomotive would be on other sections of the track both inside and outside the mines the power supply would be furnished from the trolley circuit.

Though the combination locomotive is peculiarly suited to the needs of this peculiar condition it is well to remember that it would have a place in this mine or in other mines apart from any such unusual problem having to be solved. In what follows some advantages

will be discussed that have no connection with the problem stated but would be found available in other operations. These advantages are cited so as to complete the record.

Another advantage that would not apply to the problem under discussion is as follows: Combination locomotives can be, and are, used for switching loaded cars at the bottom of shafts after the main-line motor has brought the trip to the point near the shaft where it makes a flying switch to the empty track for its trip of empties. It is also used to handle the cars on and off the cage.

Combination locomotives operate efficiently from both trolley and battery. The battery can be charged while the locomotives are operating from the trolley, except in the very low types the limited height of which does not allow room for the charging equipment.

Where a main-line motor is out of commission temporarily, the combination locomotive can take its place and keep cars moving and coal coming to the dump. Where power is not kept on the line at night the combination locomotive with the battery which has been fully charged during its operation on the trolley in the daytime can be used for the night shift to deliver men or material to any point where work has to be done, the power being furnished by the battery. Such a locomotive will soon pay for itself in general utility service alone. In case of trouble or accident, the utility locomotive is always ready to run to the scene under its own power even though the power lines may be out of commission.

In many situations, combination loco-

motives save a large investment in trolley wire, bonds and feeders by doing all the gathering and entry hauling on battery power and only operating on the trolley where the work to be done justifies the installation of wires, feeders and bonds. New mines are being laid out so that the trolley wire with its necessary feeders and bonded track is confined to the main-line hauls, the work on the cross or butt entries and in the rooms being taken care of by battery power entirely.

### Advantage of High-Voltage Distribution in Mines

In a coal mine, an electric pump is operated at a point about a mile from the foot of the shaft. It receives its power supply from a three-phase alternating-current circuit, consisting of No. 6 copper wire. The line runs down the shaft and through the gangways to a point near the pump where it delivers 2,200-volt energy to a bank of transformers. At the transformers, the voltage is reduced to 220 volts and then supplied to the pump motor. For safety purposes it is desired to reduce the distribution voltage from 2,200 volts to 440 volts and transmit the pressure at this voltage to a bank of transformers near the pump and there reduce it to 220 volts for the motor. Is this a good idea, will the pump operate as well as at present?

A SUBSCRIBER.

The size of the motor mentioned in this problem is not stated. For this reason we will have to make several assumptions. The motor is probably an induction-type alternating-current unit and an understanding of its characteristics will no doubt help us reach some satisfactory conclusions.

Most induction motors are designed and rated with the idea that they will operate satisfactorily with 10 per cent over-voltage, or 10 per cent under-voltage. Although this is true every effort always should be made to supply induction motors with normal voltage. The torque of this type of motor decreases rapidly with even a slight reduction of voltage; for example, when the motor is supplied with a pressure 10 per cent below normal, the torque decreases to about 81 per cent.

Hence, it is important that every induction motor be connected to circuits capable of furnishing as near full normal voltage as possible. This fact is not always given due consideration, and it is not at all unusual to find coal companies investing large sums of money in bigger motors than needed, in order to get sufficient torque to

Low-Type Battery and Trolley Locomotive

One important advantage of the combination-type locomotive is that it carries its own power plant and therefore causes no voltage drop for other equipment or its own motors when operating for its batteries. Full voltage can be obtained from the battery just as long as it is not discharged unduly.

Fig. 1—High-Voltage Distribution

By transmitting the energy at 2,200 volts the low currents permit the use of small wires and the per cent voltage drop is low.

operate machinery supplied from below-voltage power circuits.

This practice of over-motoring equipment driven by electric motors introduces poor power-factors and aggravates the conditions. By decreasing the distributing voltage from 2,200 to 440 volts, the current required for a given load increases to five times its original value. The Underwriters recommendations as to wire sizes show us that a No. 6 wire is capable of carrying 50 amp. To carry five times this current, a wire slightly larger than 4-0 would be required.

Although the power to be transmitted, is not stated in our problem, it is probable that the full load current in the transmission line is about 25 amp. The same power transmitted at 440 volts would therefore require about 125 amp. It is well to note that the area of the conductor, expressed in circular mils has been increased about eight times. This is due to the greater heating capacity of the larger current.

Whether the pump motor will operate satisfactorily depends not upon the transmission voltage, but upon the voltage supplied directly to the motor. The transmission voltage may be high or low, efficient or inefficient, but if the secondary voltage of the transformers

Table Showing Voltage Drop

Volts	Amperes	Wire Size	Drop 10,000 ft.	Per Cent
2,200	25	6	100	4.5
440	125	4/0	60	13.6

is 220 volts, the motor will operate very satisfactorily. Whenever the transmission voltage is low, the transmission current is high. Unless large conductors are used for carrying heavy currents the voltage drop in the transmitting circuit will be high, and the transformers will not receive the proper primary voltage. Usually when voltages lower than normal are furnished to a transformer the secondary circuit supplying the load has a correspondingly low pressure.

Assuming a simple circuit 10,000 ft. long supplied first by 2,200-volt energy, and secondly supplied by 440-volt energy. In transmitting 25 amp. of current at 2,200 volts over a No. 6 wire, the drop is above 4.5 per cent. The same power transmitted at 440 volts over a 4-0 wire has a drop of 13.6 per cent. Consequently, trans-

Fig. 2—An Expensive Circuit

Unless very large conductors are used the power loss in the line and the voltage drop is excessive. It is also unusual to transform from 440 to 220 volts. The cost of the transformers and the transformer power losses generally warrant buying a 440-volt motor.

formers supplied from the 440-volt line will receive less than the normal 440 volts and unless sufficient transformer taps are supplied in the transformer winding the secondary voltage supplying the motors will be abnormally low.

## Using Special Wheels for Polishing Materials

If a very high polish is required on a piece of material it can be obtained by buffing. Wheels used for this work are usually made of felt. There are many kinds of felt wheels on the market, Mexican gray felt being the most popular. It is relatively cheap, yet gives good service. For best results a buffing compound should be

Fig. 1—Applying Buffing Compound

To secure a high polish on a piece of material a felt wheel prepared with a buffing compound, usually of crocus is used.

applied to the wheel, as in Fig. 1. Fig. 2 shows a piece of material being polished on a soft wheel in preparation for the buffing operation. The composition used on these buffing wheels for general work is usually in the form of sticks or cakes. As a rule these cakes are compressed tallow or some other heavy grease, containing a polishing material such as tripoli, crocus, rouge, flour, emery, etc. Polishing and buffing

Fig. 2—Preparing Material Before Using Buffing Wheel

By first polishing the material on a canvas wheel the buffing operation can be made more satisfactory.

wheels are made in sizes ranging from 6 to 18 in. diameter and  $\frac{1}{2}$  to  $2\frac{1}{2}$  in. thick.

A good cement for cementing emery cloth to wooden wheels consists of  $4\frac{1}{2}$  lb. of rosin, 3 lb. of paraffin, and 9 oz. of vaseline. The ingredients are melted and mixed thoroughly. The surface of the wheel is heated and the mixture spread on the wheel. The emery cloth is then rubbed down to

Fig. 3—Box for Grinding-Machine Parts

A cabinet provided near the stand will make it much easier for the workman to put the supplies in a safe place.

exclude all air sacs. Allow the cement an hour or two to set, and it is ready for use.

To protect wheels from severe misuse they should be stored properly when not in use. In Fig. 3 is shown an inexpensive means of storing grinding-stand supplies in a convenient but substantial box. It is much better to arrange some kind of protection for these supplies than to permit them to be abused by allowing them to lie on the floor. With the storage case near the machine there is always a better chance to have the wheels put away properly.

G. H. RADEBAUGH.

## Prevents Burning of Brushes

The application of oil on the commutator of electric machines will often stop sparking. This is especially true of machines fitted with carbon brushes when the spring tension is too great. The oil temporarily reduces friction and heat but should be used sparingly.

A few weeks ago we were having considerable trouble with some brushes on our generator and I put about  $\frac{1}{2}$  in. of engine oil in a tray and placed it over one of the steam pipes in the engine house. The brushes were stood on end with the beveled edges in the oil. After the brushes had stood for a few hours they were wiped and again put on the machine. The sparking stopped immediately. I find that this treatment allows these brushes to absorb enough lubricant to operate satisfactorily for almost six months. The treatment must be repeated occasionally as the brushes wear down because the oil does not penetrate very deeply.

ELECTRICIAN.

Lubricating Generator Brushes

By letting the brushes stand in a pan containing about  $\frac{1}{2}$  in. of lubricating oil they soak up sufficient lubricant to keep them from causing any undue sparking at the commutator. This process has to be repeated about every six months because the oil does not penetrate very deeply into the carbon.

# Production And the Market

## Hesitant Tendency Holding Back Expected Revival In Bituminous-Coal Business

Clutching at any straw within reach, the coal industry rejoices that the long-drawn-out convention of the Democrats has finally come to an end and heaves a sigh of relief that the choice of a candidate fell to one not likely to indulge in rampages for regulation if his campaign for election should prove successful. Whether this is the herald of the early approach of the long hoped-for upturn in business or not it marks the passing of what in some quarters has been regarded as one of the obstacles in the path of business resumption. What the others may be, other than the usual hesitant attitude while waiting to see which way the political wind will blow, doesn't seem to be clear. At any rate, caution continues to dominate the coal business in the leading markets of the country, consumers showing a reluctance to buy except for immediate needs or when distress coal may be picked up at a sacrifice.

### Kanawha Mines Working with Lower Scale

Since twenty-six operations in the Kanawha field last week posted a scale of wages cutting tonnage rates to the same level as the 1917 rate and placing day wages somewhat above the basis of that scale six companies have resumed production. One of the most encouraging developments of recent weeks is the announcement that six textile plants are about to reopen—three in Massachusetts and a like number in Connecticut.

**Coal Age Index** of spot prices of bituminous coal sticks uncomfortably close to the unprofitable low level of recent weeks, the figure for July 14 having receded to 162, the corresponding price for which is \$1.96.

The holiday week end played havoc with traffic at Hampton Roads, dumpings of coal for all accounts during the week ended July 10 totaling 236,520 net tons, a slump of more than 165,000 tons from the previous week, when 401,935 net tons was dumped. Coal dumped at Lake Erie ports during the week ended

July 12, according to the Ore & Coal Exchange, was as follows: Cargo, 731,438 net tons; fuel, 48,062 tons. The totals for the preceding week were 712,277 net tons of cargo coal and 40,966 tons of fuel coal.

Bituminous production also received a severe setback because of the holiday, output for the week ended July 5, according to the Geological Survey, totaling only 5,755,000 net tons, compared with corrected returns of 7,371,000 tons for the previous week. Anthracite output likewise slumped, the figures being 1,296,000 net tons. This compares with 1,918,000 tons produced during the preceding week, according to revised returns.

The customary summer quiet characterizes practically all branches of the anthracite trade. Demand, as usual, is best for stove coal, being sufficient to take care of the output. Egg and chestnut also are moving well, though dependent in a degree on the call for the more popular stove. Pea, however, is causing some difficulty, many of the larger companies stocking it. Steam sizes are in weak demand. Independents' prices hold fairly firm on stove, but occasional concessions are made to move the less active sizes. A number of the smaller independent operations, it is reported, have not resumed production since the holiday because of the falling off in demand.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
June 21 .....	10,422,000	7,202,000
June 28 (a) .....	10,458,000	7,371,000
July 5 (b) .....	8,742,000	5,755,000
Daily average .....	1,748,000	1,151,000
Cal. yr. to date (c) .....	279,553,000	231,971,000
Daily average to date .....	1,770,000	1,469,000

#### ANTHRACITE

June 21 .....	2,042,000	1,823,000
June 28 .....	2,105,000	1,918,000
July 5 .....	1,580,000	1,296,000
Cal. yr. to date .....	52,749,000	46,921,000

#### COKE

June 28 (a) .....	399,000	125,000
July 5 (b) .....	376,000	95,000
Cal. yr. to date (c) .....	10,378,000	6,177,000

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Lives on Hope

Nobody made any money out of the Midwest coal market during the past week. Trade could hardly be any deadier. Last week's slight increase in Illinois, Indiana and Kentucky production was not at all well received. A slight firming up of steam sizes was noticeable for a few days, but even that did not last. Domestic business is absolutely flat. The trade continues to count on inevitable business cropping up any day.

Smokeless business is sagging a little more. The \$2 mine price on mine run is not attracting anybody and the little coal that is moving is forced at less than that in spite of circular. Anthracite also is dead. The first real hot weather of the summer in the Chicago region and continued heat in the belt from Des Moines and St. Louis east across Iowa, Illinois and Indiana kills about all the retail yard business there is.

Southern Illinois producers are not expecting much from the new move in the Northwest to get the I.C.C. to reconsider its recent rate decision which hiked the cost of shipping by rail into Minnesota. They are counting on the increase to take effect Aug. 21, as scheduled, and expect to see some business taken away from them by the docks.

Continued quietness prevails over the entire southern

Illinois field. Everything is practically at a standstill, outside of a little railroad coal. "No bills" of all sizes are on hand and mines that a few weeks ago were getting a couple of days a week are practically idle. A little movement to the Northwest is noted occasionally on lump and egg. The same conditions prevail in Duquoin and Jackson County.

The Mt. Olive field is shipping on a few railroad contracts to the Northwest. The Standard field also is at its worst. Everything seems to have come to a dead stop. All sizes are on track and coal is sold below cost and the trade is hopeful that things will soon begin to pick up.

In St. Louis the usual midsummer vacation period has just about killed the retail coal business. There is absolutely nothing doing, except the public-school business and a little apartment storage. Country domestic begins to show signs of a little life, but country steam is pretty well shot.

### Kentucky Is Whistling

Generally speaking business at Louisville is showing some signs of life, there being better inquiry and better general outlook, but there hasn't been much increase in tonnage. The steel and metal-working industries continue buying slowly along with the auto, ice and cold-storage interests, while railroad consumption appears to be a shade off and utility movement would not indicate that the utilities are

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	July 14	July 7	June 30	July 16
Index .....	162	164	166	198
Weighted average price....	\$1.96	\$1.99	\$2.01	\$2.40

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

rushed. General movement from eastern Kentucky has been quite fair, in spite of the fact that the movement to the Lakes doesn't show up as well as that of last year.

Retailers have been getting a better volume of business, but locally and in districts close to coal fields the retailers appear to be buying for immediate use and making no effort toward yard stocking. Movement to the Southeastern textile districts continues dull, as the textile trade is not busy. However, there has been some very fair scattered movement to Michigan and as far as Canada, moving over three and four railroads in some instances, and some movement West and Northwest. Prices show no change.

In western Kentucky the situation is not inspiring. Although four of the St. Bernard mines are trying to run non-union, the production of the field is not picking up much. The strike paralysis grips most of that end of the state. The strip mines are doing fairly well, however.

Smokeless originating in southern West Virginia occupies a relatively stronger position than high volatile. Smokeless output is about 700,000 tons a week, nearly half of which is coming from the Pocahontas region. There continues to be a strong demand for low volatile lump and egg. There is not much activity in the buying of high-volatile fuels except for the tonnage moving to lake points.

### Northwest Idles Along

Trade is still dull at Duluth. Kentucky lump has dropped to \$6, splint run of pile is up to \$5 and Pocahontas mine run is off to \$5.25. These prices are not considered as indicative of anything but slight readjustment. The de-

mand from steam plants which have been compelled to operate because of the low water has fallen off and docks are feeling the loss of this trade.

Railroads are taking lots of dock coal. Shipments last month ran to 13,401 cars. In all about 90,000 cars went out the first six months of this year as compared with 66,000 in the first six months of last year.

The docks will have to hurry if they are to have enough coal to go around this year, according to comparative figures of the past few years. About 7,000,000 more tons is needed, as only about 2,000,000 tons of all sorts of coal has been brought up so far, and about 3,000,000 tons was on the docks when the season opened.

Anthracite is very dead. It does not seem possible to make the buyers start laying in their winter's coal.

The general free-for-all on prices at the Twin Cities seems to have reached the point where general blood-letting was not beneficial to any of the patients, and there is something of a stiffening. Dock prices are around \$3.75 for screenings and \$5.75 for Youghiogheny lump and \$5.25 for Hocking lump. All signs point to a reaction that will give the coming autumn a better demand than has been experienced in several seasons. Commercial and industrial conditions are fairly promising and crops generally seem to be in good shape.

The Milwaukee coal market is at a normal summer level, which means monotonous dullness. Hopes of a betterment during July have been dissipated. There have been no changes in prices. Cargo receipts of coal by lake since the opening of navigation have passed the million-ton mark, the aggregate up to date being 329,538 tons of hard coal and 699,083 tons of soft coal, or 1,028,621 tons in all. This total is about 50 per cent less than the total up to this date last year.

### West Generally Quiet

Little activity is reported through the Southwest. The demand for threshing coal, as compared with that of other years, has been good, but this takes a small volume of fuel. During June there was some storing of domestic coal, principally semi-anthracite, by householders. Dealers, however, apparently were buying only to supply the current demand. This remains steady in spite of a 50c. increase in the retail price of Arkansas semi-anthracite to \$11.35. No change has occurred in wholesale quotations, which remain \$5.50@\$6 for lump, \$3.25@\$3.75 for mine run, and \$2 for screenings.

Kansas coal prices are: Lump, \$4.50; nut, \$4; mine run, \$3.50; and screenings, \$2.50. Henryetta (Okla.) coal is: Lump, \$4; nut, \$3.50; mine run, \$3; and screenings, \$2.

Very little change is noted in Colorado except for a slight pick-up in the movement of coke. Mines worked on an average of 20 hours last week and attributed 46 per cent of the working time lost to "no market." Prices remain unchanged.

Salt Lake City coal dealers have increased their prices as follows: Utah lump, \$8@\$8.75; domestic lump, \$7.50@\$8.50; nut, \$7@\$8; pea coal and slack remain \$6 and \$5 respectively. Stove coal, which has been retailing at \$7.25, will not be made hereafter. The announcement of this increase has increased the storage orders slightly.

### Bottom Drops Out at Cincinnati

The bottom has dropped out of the Cincinnati market. Steam buyers are not even interested in very low spot quotations, most of them having ample unused reserves, due to suspended or considerably reduced operations. Domestic retailers, who had placed large orders for July delivery in the belief that the usual buying by the householder would be in evidence this month, are canceling most of these orders because the customary business has not shown up for them, while there is an almost complete dearth of new orders. The usual volume of thresher's coal is going out, but the farmers are not buying winter supplies.

Buying at Columbus is limited to present needs and there is little to break the monotony. Domestic demand has slumped. What coal is moving is mostly of the smokeless varieties and splints. Hocking and Pomeroy grades are exceedingly dull. Retail prices are fairly steady at former levels. Little change has taken place in the steam business. Many of the heavy users are not in the market, as consumption in many lines has been reduced owing to industrial conditions. Utilities and railroads are the best

users. Contracting is not much, as most of the buyers are picking up cheap consignments of distress coal. School coal is moving in fair quantities. Lake trade is steady, although there is a plentiful supply of bottoms.

Demand is lackadaisical at Cleveland. Despite various quantities of distress coal appearing from time to time, spot prices continue stable. Business conditions are no better; if anything, they are slightly worse, judged by the barometer of railroad traffic. The producing end of the trade is optimistic in the belief that the next change in conditions will be upward, because fuel preparations for the coming autumn and winter must shortly begin. While some more small mines have closed, there are reports of resumption by some of the larger companies, one company with two mines of 1,800 tons per day capacity starting up this week.

Further stagnation has hit the Pittsburgh market. Even local consumption has declined enough to make a difference in the total operation of the district, which has been running at but little above one-eighth of capacity, against about one-fifth in April and May. Of domestic demand there are as yet practically no signs.

Industries at Buffalo that have been losing ground considerably of late find no consolation from the coal trade. It is at the bottom and seems to be finding a new and lower bottom now and then.

### New England Trade Light and Fitful

To New England buyers there seem to be no present inducements. The industries are under severe curtailment because of lack of business, and not yet is there enough prospect of better markets to warrant purchases of fuel beyond ordinary summer reserves. A few of the smaller textiles have so reduced their stocks of coal that they are making inquiry for September and October delivery, but there is no volume to this business and it will only replace the tonnage which still other plants of the same character will stop taking.

At Hampton Roads there is no special change. Accumulations are only moderate, but spot sales are by no means dependable. It is only the staple contract trade that is absorbing its share of current output, and there is still some fluctuation of prices in the effort to make sales that will move demurrage coal. No. 1 Navy standard coals can be bought at \$4.25@4.40 per gross ton f.o.b. vessel, with second grades at 15@35c. less. The larger agencies are following a very close-hauled policy in the effort to avoid being pressed to move current output.

For inland delivery at this end there is little to report. The dullness that has now spread over so many months has discouraged for the most part the practice of forcing cargoes on a reluctant trade.

All-rail from central Pennsylvania there is a little business being done by standard shippers who are both anxious to keep mines in operation at least a part of the time and are willing to meet conditions. A few of the quality grades from Cambria County are selling well down to \$2 per net ton at the mines, but the market in this territory is still restricted to points well away from tidewater.

### Demand Weak in Atlantic Seaboard Markets

Lack of demand, low prices and an accumulation of coal characterize the New York tidewater market. There have been daily averages of between 1,500 and 1,600 cars of coal at the local piers, with the result that in order to save demurrage charges some shippers find it necessary to let

their holdings go at less than current quotations. Many soft spots are reported, but market quotations are about on last week's basis. Reserve stocks are dwindling and consumers continue to withstand the warnings to replenish, hurled at them from all directions. Demand along the line continues slow and uninteresting. Spot coal buyers are scarce and most of the output moves on contract.

The holiday shutdown was of scant help to the Philadelphia market. Despite the lack of buying, there are evidences of better times. Shippers report an increase of inquiries for prices lately, and have been able to develop some business from them. There has also been a stir among the utility consumers. Prices remain at last week's quotations, and seem to be a trifle firmer. The market for tide coal is unchanged; bunkering, the chief business, is only moderate in volume.

The trade at Baltimore is about on the same level as for two months past. Encouragement is taken in the gradual but sure depletion of surplus industrial stocks. The three-day holiday caused a depression in the export trade, only three ships clearing with coal cargoes up to July 10, but the month bids fair to compare favorably with June.

The Birmingham market continues sluggish. There is little demand for any grade of coal, the spot market affording an outlet for only a small tonnage of either steam or domestic sizes. Consumers are buying only immediate requirements and there is practically no stocking by any of the contract consumers.

### Anthracite Feels Dull Season

The anthracite market at New York is comparatively quiet. The demand depends greatly upon the call for stove coal. Egg and chestnut move freely, but they are taken mostly in conjunction with the other large sizes. Independent broken coal is practically out of this market, many operators finding it necessary to break it in order to prevent accumulation. Independent operators are able to get about \$9.50 for straight lots of stove coal, but when taken with either egg or chestnut quotations are 25c. to 50c. lower. Pea coal is causing some trouble to certain of the smaller operators and some of the larger companies are sending it to stockpiles. There is little call for steam sizes and independent product is being quoted at lower figures by those small operators who continue to produce coal.

The situation in Philadelphia has grown quieter. In another week some curtailment of mining by independents probably will be necessary. The dealers' yards are filled with all sizes, and even stove is not in such demand as it was a few weeks ago. Steam sizes are so extremely slow that some shippers are selling buckwheat below \$2.50 in order to get it out of the way, and rice is in almost the same position. Barley is a trifle better, but there is even a slowing down in the demand for this size.

The raise in hard-coal prices on July 1 seemed to have very little effect on trading at Baltimore. The usual number of July orders are being placed in the majority of cases, although some dealers complain that they are considerably behind the annual average.

## Foreign Market And Export News

### British Market Continues to Improve; High-Cost Operations Close

The south Wales coal market has improved only slightly during the last week, and business is still far below the capacity of the industry. European exchanges are steadier and some of the higher cost pits have been closed, so that production expenses on the whole are slightly lower. The Welsh operators are emphatic that any reduction in price is out of the question on account of the increased working costs under the new agreement. In some cases they are endeavoring to speed up production at the newer pits by the adoption of the two-shift system, but the miners are strenuously opposing any such innovation, and it is likely that sectional strikes or lockouts will result. The Miners' Federation seems to be in rather bad odor and is losing members, so that the agents are getting busy on a campaign to force every miner in Wales into the Federation. Notices soon to be given in the Rhondda district will affect about 45,000 men. Inquiries from Belgium and France have increased, and there is some more business with Italy.

Business in the Newcastle market is slow; the collieries are engaged mainly in filling old contracts. It is stated that the Paris gas works has contracted for the supply of 70,000 tons of Durham gas coals at 20s., delivery to be over the rest of the year.

Coal output by British mines during the week ended June 28, according to a cable to *Coal Age*, was 5,170,000 tons, compared with 5,173,000 tons produced during the previous week.

#### Trade Slows at Hampton Roads; Optimism Wanes

The situation at Hampton Roads is extremely dull, with comparatively no demand for spot coal and with the market showing a decided tendency to weaken. Some coastwise movement has been noted, but on contract, while foreign business continues in the slump

it struck two weeks ago when large orders for Brazil were completed.

General shipping appears to have struck a period of dullness which is reflected in poor bunker trade. Supplies are accumulating at the piers, the post-holiday production having begun generally in the mines serving this terminus. Shippers are not optimistic over the immediate outlook.

#### French Market Maintains Favorable Position

The situation of the French collieries has now been favorable for several months, although there was a slight unsettlement when the rates of sterling depreciated to 67-68 fr., thus putting British and French coals on a fairly level price. But since May 8 the pound has recovered and the price of these two fuels has shifted to the advantage of the latter. Therefore, if French coal seems to be well sold at present, this is due more to a slackening of output than to a question of price. Activity in household coal is rather good, so that few disposals are recorded outside of contracts.

There is fair inquiry for British anthracites on the Paris market, in spite of the prices being still affected by the high value of sterling.

In Belgium, house coals are well sustained while the industrial coal market is easier for the same reasons as prevail in France, and there is a disposition to take a hopeful view regarding the possible maintenance of prices in the autumn.

With the stoppage of the canals and a rather short supply of boats, freight is higher at 22 fr. Bethune-Paris.

Deliveries of indemnity fuels during May to France and Luxemburg included 243,400 tons of coal, 365,300 tons of coke and 333,900 tons of lignite briquets, a total of 642,600 tons, as compared with 1,301,100 tons in April.

The supply of indemnity coke to the

O.R.C.A. for the first twenty-four days of June was 312,278 tons, a daily average of 13,000 tons, showing an increase over the May deliveries and on the early part of June.

## News Items From Field and Trade

### ALASKA

The Geological Survey has begun its 26th successive year of the investigation of the mineral resources of Alaska. During this time it has mapped the topography and geology of over one-third of Alaska's total area of 586,400 square miles. It has investigated in at least a preliminary way every producing mining district in Alaska, and has mapped many of these in detail. Since 1905 it has annually collected and published the statistics of mineral production of the territory. The results of this work are published in 380 different reports and over 400 maps, which throw much light on the resources, including water supply, as well as the topography and geology of Alaska. A detailed topographic survey is being made of the Hyder district, of southeastern Alaska, by R. M. Wilson, topographic engineer. A. F. Buddington, geologist, is continuing his investigation of the geology and mineral resources of southeastern Alaska. This year he will investigate parts of the Ketchikan, Wrangell, and Juneau districts. S. R. Capps, assisted by Kenneth Landes, is making a supplementary examination of the Matanuska coal field.

### ARKANSAS

The Meard and Bevil mine near Bates is being pumped out and arrangements are now being made to operate it after a suspension of 10 months.

It is hard to believe that District No. 21 of the United Mine Workers, covering Arkansas, would violate a contract, but Webb Covington says it violated its two-year contract to employ him at \$7,500 a year as the district's chief attorney. So he is suing for a year's pay.

### CALIFORNIA

With the price of oil mounting, California is taking more interest in its coal. Lloyd L. Root, state mineralogist, recently issued a statement in which he said the California coal deposits were estimated at one billion tons and that a total of 5,177,125 tons has been extracted. He calls attention to the presence of iron ore in Shasta, Madera, Placer, Riverside, San Bernardino and Mendocino Counties and says: "The lack of cheap coke makes it impossible to use these ores commercially. There is a good future in the iron and steel industry in this state when coke can be obtained economically." He says there has recently been a little prospecting for coal in the Ione field of

Amador County; at Tesla, in Contra Costa County; at Stone Canyon, in Monterey County, and at Palo Cedro, in Shasta County, but that the only development of importance has been made this year in the 14-ft. seam of sub-bituminous coal at Dos Rios, Mendocino County.

### ILLINOIS

A strike of 100 miners at the Shuler Mining Co., of Alpha, has been settled and the men have returned to work. The mine will now be operated about three or four days a week.

Peabody Coal Co. mine at Marion recently broke its hoisting record with a total of 2,892 tons in one day, filling 59 railroad cars and requiring 1,394 dumps.

William Kortkamp, Sr., veteran coal operator of Montgomery County and widely known throughout that territory, was recently appointed county mine inspector by the County Board of Supervisors.

A mine may be sunk soon at Ashland, as a company of business men has been formed at that town to start the enterprise. Officers are F. C. Walbaum, president; H. J. Loman, secretary, and J. N. Blank, treasurer.

The Wittenborn & Carter Coal Co. has completed its tippie and is now handling three grades of coal. This mine is located on the Wittenborn farm, three miles south of Cutler, on the Duquoin and Chester state road.

It has been announced that the St. Louis Coke & Iron Co., now operating blast furnaces and eighty coke ovens at Granite City, will add another blast furnace to its plant at that place. This plant expansion will cost approximately \$2,500,000 and it is the intention of the company to turn the gas from the blast furnaces into electrical energy, which will be sold to public utility corporations in southern Illinois and Missouri. Southern Illinois coal is used exclusively in the plant at Granite City.

The Jefferson Southwestern Ry., built recently by the Illinois Coal Corporation to connect its new mining town of Nason with Mount Vernon, 11 miles distant, has not yet freed itself of operating limitations. It was built last year in the face of other railroad opposition. Although it obtained permission of the Illinois Public Service Commission to operate in intrastate traffic, it has been able to make joint traffic agreements only with the C. & E. I., the L. & N. and the Southern and it is still petitioning the Interstate

Commerce Commission for the right to participate in interstate traffic. This petition has been denied once, but on an appeal the commission decided to permit operation under certain specific restrictions. The railroad's second appeal to have these restrictions lifted has been in for about two months and another decision is expected.

An effort is being made to reorganize the Lovington Coal Mining Co., which is now in bankruptcy. The company has a mine and about 5,000 acres of coal rights at Lovington. It is stated that stockholders in the present company will realize very little from their claims.

### KANSAS

It is still possible, under the Kansas Industrial Court law, to jail a man for calling a strike in an essential industry just as Alexander Howat was jailed. The Kansas Supreme Court reached this decision July 5 after a rehearing of the case of August Dorchy, Howat's lieutenant, who was jailed with him two years ago. Howat has been pardoned but Dorchy took an appeal. The Kansas Supreme Court decided that even though the United States Supreme Court last fall declared the wage-fixing section of the Kansas law unconstitutional, the balance of it stands alone and remains in effect.

### KENTUCKY

A large commissary store operated by the Black Diamond Mining Co. at Drakesboro was one of several stores in the town to burn in a \$100,000 fire on the night of July 6. The company mines have been down for some weeks on account of the district strike.

Fred M. Sackett, prominent coal operator, retailer and jobber, of Louisville, has named the advisory committee to aid him in his race for the U. S. Senate on the Republican ticket. Denver B. Corbett, of Harlan, is one of several coal-mine operators included.

The Harlan Coal Co., Louisville, on July 7, lost a suit pending since 1920, following a five-day argument, in Judge Gordon's court, in a suit for \$75,000 damages against the Wheeler Coal Co., of eastern Kentucky, in which the Louisville company alleged violation of a contract. The petition was filed on Aug. 2, 1920.

The Hatfield-Reliance Coal Co., which succeeded the Reliance Coal & Coke Co. some weeks ago in a merger of the Reliance and Hatfield interests of Cincinnati, is reported to have been

enlarging its mining plant at Glomawr, four miles from Hazard. The company has completed sixty additional miners' homes and plans increased output through new mines already opened.

A petition for writ of error and right to appeal to the U. S. Circuit Court of Appeals of the Sixth District at Cincinnati was granted the Fordson Coal Co. in its suit against the Kentucky Coal Lands Co. and others, by Judge A. M. J. Cochran, in the U. S. District Court at Lexington, Ky., July 2. This followed Judge Cochran's denial of writ of possession and overruling motion for possession by the Fordson Coal Co. of the lands under litigation in Leslie County valued at \$100,000. In his judgment against the Fordson Coal Co. Judge Cochran ordered that the plaintiffs pay all court costs. In granting the appeal to W. K. Middleton, of Detroit, one of the lawyers in the case, Judge Cochran set the date for the Cincinnati filing for Sept. 1.

## NEW YORK

Mayor Schwab, of Buffalo, has recommended the putting of automatic coal burners into the furnaces at police headquarters and the various station houses about the city, at a cost of about \$10,000. Certain sample burners used by the city are said to have effected a big saving.

## OHIO

F. S. Davidson, formerly with the Gibraltar Coal & Coke Co., has taken service with the Columbus office of the Elk River Coal & Lumber Co. George A. Ramsey, formerly in the jobbing business in Columbus under the name of the George A. Ramsey Coal Co., also has joined the staff of the Elk River Coal & Coke Co., and will cover the State of Indiana.

A conference of the joint committee representing operators and miners in the Hocking Valley field was held at Logan, Ohio, last week, starting July 8. An entire new set of rules containing many radical changes from those formerly in force was presented for discussion. The matter was considered for the remainder of the week without arriving at any decision. It is believed that some conclusions may be reached which will mean the opening of a number of mines in the southern Ohio field.

Columbus coal operators were advised recently that more vessels are being offered at Toledo and Sandusky ports than are needed for the transportation of coal to the Northwest. Part of this excess tonnage of shipping is due to the fact that Ohio mines at the present time are producing very little lake coal, owing to a scarcity of orders. Heavy tonnage of lake coal continues to pass through Columbus from the non-union mines at West Virginia and Kentucky to the docks at Toledo and Sandusky.

## PENNSYLVANIA

Fire of unknown origin destroyed the tippie at the Pittsburgh Coal Co.'s Partridge mine, near Allegheny, early on July 4. The mine has been idle since last autumn.

W. J. Rainey, Inc., resumed operations early last week at the Allison No. 1 plant, which was one of the plants closed down the week before because the men refused to continue at work at the 1917 scale. The men returned to work at that scale, however.

The Gulf Co. coal mine at Marion Center, Indiana County, resumed operations during the last week in June as a non-union mine. The Gulf Co. some time ago proposed to its 150 miners that they accept a reduction of wages to the scale of 1917. The proposition was rejected and the men struck.

All arrangements have been completed for the transfer of the plant of the Worthington Pump & Machinery Corporation at Hazleton to the Pennsylvania Power & Light Co. The sale of the property became effective on July 1.

The Clearfield Bituminous Coal Corporation, Indiana, Pa., has abandoned the colliery located in the Clymer-Dixonville field on the Cherry Tree & Dixonville R.R. heretofore operated under the name of Sample Run Mine. It has been replaced by a new, modern, well equipped operation to be known as Clymer No. 1.

A severe rain and windstorm on June 25 caused damages estimated at \$300,000 in the Shenandoah district of the anthracite field. The roof of the Shenandoah City colliery of the Philadelphia & Reading Coal & Iron Corporation was torn off and machinery knocked out of alignment while the Plank Ridge washery was completely

demolished. At the North Mahanoy colliery the storm did damage estimated at \$40,000. A pipe line and the stacks from the boiler house were thrown through the engine house and into the machinery of the colliery.

It was reported on June 24 from Lotts Creek that Charles Lynch, mine superintendent for the Ajax Coal Co. and Superior No. 4 Co., was shot and killed by John Vermillion, merchant at Lotts Creek, the killer claiming self-defense. Lynch was formerly from Tennessee.

The Republic Iron & Steel Co. has closed down the only mine it had been working at Russelton, in the Freeport district, which means that the only active operations of the company are one mine at Bowood and one at Martin, which are doing pretty well. The Ford Collieries Co., at Curtisville in the Freeport district, has one out of three mines working.

It is reported that the Monessen Coal & Coke Co., a subsidiary of the Pittsburgh Steel Co., is negotiating for the purchase of the Lilly Coal & Coke Co., operating a large modern mine in the Pittsburgh vein of coal, near West Brownsville, Washington County, on the Monongahela River and the Pennsylvania R.R., with facilities for either river or rail shipments. Thomas Elliott, of Brownsville, is president of the Lilly Coal & Coke Co.

Charles O'Neil, secretary of the Central Pennsylvania Coal Producers' Association, returned to his office in Altoona after a two weeks' absence. Mr. O'Neil was a delegate from the Blair-Bedford Congressional district to the Democratic National Convention in New York.

All mines of the Consolidation Coal Co. in the vicinity of Meyersdale, Somerset County, were closed for a period of two weeks beginning July 7. This is the first shutdown of the mines since work was resumed in April after a long period of idleness. At that time the miners accepted a substantial reduction in wages. No reason was given for the shutdown.

Officials of the Lehigh Valley Coal Co. have decided to resume the first-aid contests held years ago but not so prominently featured during recent years. They have made reservations for Hazle Park, Hazleton, for July 21 and 22 for the events.

Figures for the first half of the present year for the central Pennsylvania bituminous district show that the loadings were 337,271 carloads, a loss of 114,154 carloads compared with the corresponding period of 1923. It was expected that production would gain in June, but figures compiled by the Central Pennsylvania Coal Producers' Association, Altoona, show a loss of 49 carloads from May, the figures being May, 49,533, and June, 49,464 car loads. These figures indicate about 45 per cent of the maximum production and about 60 per cent of the normal production of the district.

Heilwood won first place in the tenth annual inter-plant first-aid meet of the subsidiary companies of the Bethlehem Steel Corporation, held at Johnstown June 28. Heilwood had a percentage of

Monarch Tipple, Sheridan-Wyoming Coal Co.

Coal from this mine finds a market in Wyoming, Iowa, Nebraska, Montana, Washington and North and South Dakota.

Courtesy U. S. Distributing Corp.

95.2. The Preston division team from Masontown, W. Va., was second, with a percentage of 92.6. The Ellsworth division team was third with a percentage of 92.2; Marion division had fourth place with a percentage of 91.8; Johnstown was in fifth place with 91.6, and Wehrum was sixth with 90.

## UTAH

The United States Fuel Co., of Salt Lake City, has bought a herd of cows to furnish milk for the coal mining camp of Hiawatha. A modern barn and every facility for operating a successful dairy for the camp has been installed.

There is to be no increase in the rate for workmen's compensation in Utah, according to a decision just rendered by the Industrial Commission. The decision took into consideration the safety provisions adopted since the Castlegate catastrophe last March, it was stated. A formal statement was to the effect that the experience in Utah justifies continuance of the rate of \$3.90 per \$100 of payroll. Figures were compiled by the National Council on Compensation Insurance.

## WASHINGTON

Mel C. Butler, of Seattle, is beginning to develop six sections of coal land south of the Wilkeson mine and east of Carbonado. He says this work is for the new Pacific Coal & Coke Co., which is said to be ready to build a blast furnace near Enumclaw if the coal land pans out.

The annual first-aid and mine-rescue meet for western Washington is scheduled for Carbonado on Aug. 9. About 25 teams from Bellingham, Black Diamond, Burnet, Carbonado, Fairfax, New Castle and Wilkeson are entered. The committee in charge of affairs is headed by David C. Botting, of the Pacific Coal Co. His principal aides are A. G. Harvey and A. E. Holden.

Activity at the marine coal bunkers of the Pacific Coast Coal Co. the week before last exceeded anything of like nature there for many months. On Sunday morning the Norwegian freighter Balto berthed for coaling. Immediately following the Balto, the Holland-America steamer Moerdyk was bunkered. Both vessels took on large supplies, as both are bound for the United Kingdom and European ports. On Monday and Tuesday two large Nippon Yusen Kaisha passenger liners, the Mishima Maru and the Kaga Maru, called to load bunker coal for the return trip to Japan.

The Morton Coal & Coke Co. mine near Morton is producing again. It has been leased to Peter Pagolious and A. Flewelling, of Centralia. The mine output may be brought up to about 100 tons a day. Pagolious, a Greek, who is managing the property, has some ideas about "foreigners" in this country. He came from Greece 16 years ago and is an American citizen. He thinks all other aliens in the United States should decide, by the time they have been here five years, whether

they want to stay or return to their native land. If they want to stay they should become American citizens at once. He gathers his own men together in the mine every once in a while and preaches this doctrine.

## WEST VIRGINIA

The Raleigh-Wyoming Coal Co., of which Carl Scholz is vice-president and general manager, is sponsor for an interesting monthly paper, the *Edwight Eagle*, published with a view to establishing closer relationship and better understanding between the company and its employees.

There were 27 persons killed in the mines of West Virginia during May, according to a compilation by R. M. Lambie, chief of the State Department of Mines. Of that number, 11 were killed by falls of slate, roof and coal; seven by mine-car accidents; two in motor accidents, and three by electrical shock. Four deaths, occurring outside the mines, were the result of railroad car accidents and electrical shock.

The Fairmont-Chicago Coal Co. has begun to load coal over its new tippie at the Chesapeake mine, near Barrackville, in Marion County. The mine's capacity is 1,200 tons a day, but arrangements are being made to increase the tonnage by the beginning of the year to about 2,000 a day. The new tippie cost \$100,000, is of fireproof construction and is equipped with shaker screens, picking tables, loading booms, etc., it being possible to prepare seven different kinds of coal and to load three different sizes simultaneously. The tippie is operated through a system of electric push buttons, making it possible to stop the tippie machinery at any time from almost any point.

## WYOMING

Here is a new form of mine accident. Chester Tynski, mine worker, 18 years of age, was instantly killed at Winton, Sunday, June 29, while flying a kite. The young man was using some No. 17 enameled copper wire, taken off a Ford automobile generator, as a kite string, the kite and string falling across a 33,000 volt transmission line with fatal results to Tynski, although artificial respiration was used for an extended period in an effort to resuscitate him.

## CANADA

The mines of the Inverness Coal & Railway Co. at Inverness have been closed indefinitely, owing to demands of workers and market conditions. Efforts are being made to have the company reopen the mines on a part-time basis. These mines are the sole support of Inverness, an out of the way and isolated point on Cape Breton Island.

An explosion in the Allen shaft of the Acadia Coal Co., at Stellarton, N. S., on June 30, caused the death of four men and injuries to seven. These eleven men were entombed by a fall of coal in No. 3 level, about 1,200 ft. down. According to the statements of officials

of the company, there were seventy-four men in the mine when the explosion occurred, the other sixty-three making their escape. The damage to the mine was not as great as at first supposed. Company officials believe that operations will be resumed in three or four weeks.

## Obituary

According to word received in Fairmont, W. V., Dan R. Lawson, formerly secretary of the Northern West Virginia Coal Operators Association and district fuel representative of the United States Fuel Administration during the World War, died at the family residence in Philadelphia, following an attack of appendicitis. Mr. Lawson had resided in Fairmont for a number of years. He was connected at various times with the John Y. Hite and the C. D. Robinson coal interests, with the J. E. Long interests of Clarksburg, and with the Cortwright Coal Co. in Philadelphia. For many years Mr. Lawson was connected with a railroad in Chicago. A few years ago he helped organize the Appalachian Fuel Co., with headquarters at Fairmont.

C. M. O'Dell, chief engineer for the Dominion Coal Co., died at Sydney, N. S., on June 24 after a long illness, at the age of 63 years. He went to Glace Bay in 1886 in connection with the construction of the International Railway.

Wright Lawford, mining engineer for the Bottom Creek Coal & Coke Co., in the Pocahontas field, was instantly killed last week by a slate fall in the mine where he was at work. He was 25 years of age, having been born at Pocahontas, educated in the public schools of Pocahontas, at the Episcopal High School in Alexandria, Va., and received his engineering degree from the Alabama Polytechnic Institute at Auburn, Ala. For a time Mr. Lawford worked for the Pocahontas Fuel Co., becoming a mining engineer for the Bottom Creek Coal & Coke Co. about two years ago.

Herbert Bertrand Wright, long and prominently identified with the mining industry of southern West Virginia and southwestern Virginia died at his home in Pocahontas on Monday, June 30. Death followed an illness of about a year's duration. Mr. Wright was born on June 18, 1863, at Bury, Quebec. He received his education in the public schools of Quebec and at Eaton Academy, Eaton, Quebec. He later became a naturalized citizen of the United States. In 1893 he became superintendent of construction and operation of a mine belonging to the Elk Ridge Coal Coke Co. in McDowell County. From 1918 until the time of his death he was chief engineer in charge of all engineering work of the Pocahontas Fuel Co. He also was a vice-president of the Excelsior Coal Co. From 1896 to 1899, Mr. Wright was the manager of the Peerless Coal & Coke Co., at Vivian. In 1902 he became chief engineer in charge of surveys, prospecting, etc., on some 20,000 acres of coal lands for the Faraday Coal & Coke Co. His wife and one brother survive.

## Traffic News

### Want Northwest Rate Case Reopened

Application has been filed with the Interstate Commerce Commission by the Northern States Power Co., as a large user of all-rail fuel, for a rehearing in the case of the dock companies against the carriers for an adjustment of the discrimination alleged to exist in the freight rates from the docks and from the southern Illinois mines to the Twin Cities. The Minneapolis Traffic Association and the St. Paul Association also have intervened with a request to reduce the rate from the docks on soft coal, now \$1.82 for 150 miles, to \$1.50, rather than increase the all-rail rate, now \$3.47 for 630 miles, to \$3.75.

It is something of a question as to whether the commission will grant a rehearing after the recent complete consideration of the case, but it seems possible that there may be a resort to the courts by the all-rail shippers. That would hardly come until close to the time for the proposed change, August 21, when a temporary injunction might be asked, that would throw the case back until a court hearing. The carriers are proceeding with their arrangements for instituting the new rates.

### Hearing on Iowa Petitions for Lower Rates Completed

The long freight-rate hearing on various Iowa petitions for reduction of rates from many fields to Iowa have been completed. The sessions of the Interstate Commerce Commission examiner ran both in Des Moines and in St. Louis, Mo. A decision is expected by autumn.

### Alton Cuts Rate from Illinois To Kansas and Missouri

To enable Illinois operators to compete with Kansas coal operators for the Kansas City and St. Joseph (Mo.) trade, the Chicago & Alton R.R. is about to reduce the freight rate on fine coal from central Illinois 9c. a ton. The old rate was \$2.07 and the new rate is \$1.98. Some weeks ago the Southwestern district operators obtained a 9c. reduction from Kansas and Oklahoma. Immediately the Alton gave notice that it would voluntarily file notice of a reduced rate to take effect Aug. 7. This rate has now been published.

### Circuit Court Disallows Cut In Illinois Rates

The cut in coal rates between Springfield and Bloomington, Ill., ordered recently by the Illinois Commerce Commission was reversed by Judge E. S. Smith in Circuit Court at Springfield, July 2, and referred back to the commission for reconsideration and the taking of more evidence. The commis-

sion, upon the petition of the Bloomington Association of Commerce, reduced the rate from \$1.42 to 80c. A proportionate cut was made in the rate between Lincoln and Bloomington. The railroads objected to this as unreasonable and appealed to the Circuit Court.

## Association Activities

D. F. Buckingham, general manager of the Roslyn Fuel Co. and the Independent Coal & Coke Co., 818 White Bldg., Seattle, was elected president of the **Washington Coal Producers' Association** at its annual election held June 17. He succeeds E. P. Lucas, general manager of the Bellingham Mines, who has headed the association's activities for the past year. Prescott Oakes, treasurer of the Roslyn Fuel Co. and the Independent Coal & Coke Co., was re-elected as treasurer, and W. E. Maltby was again named manager of the association.

John C. Reid of the Cameron Coal Company, McAlester, Ok., was elected president of the **Southwest Interstate Coal Operators' Association** at the annual meeting of that organization. Approximately seventy-five members of the association from Missouri, Arkansas, Kansas and Oklahoma attended the meeting. Business of a routine nature, affecting the coal industry in the Southwestern field, occupied the attention of the members present for the one-day convention, according to W. L. A. Johnson, general commissioner of the organization, who was re-elected.

Practically all of the coal operators of Colorado and New Mexico met June 18 at Denver in the sixth annual meeting of the **Colorado-New Mexico Coal Operators' Association**, reviewing the year's work and taking a look ahead. The association re-elected F. O. Sandstrom secretary-treasurer and traffic manager. The officers for the ensuing year, in addition to Mr. Sandstrom, are these: President, F. R. Wood, president of the Temple Fuel Co.; vice-president, H. F. Nash, vice-president of the Oakdale Coal Co.; directors, W. D. Brennan, of the Phelps-Dodge Corporation; Frank Bulkley, of the Baldwin Fuel Co.; L. A. Hayden, of the Hayden Bros. Coal Corp.; W. H. Huff, of the Victor-American Fuel Co.; A. M. McNeil, of the McNeil Coal Co.; S. S. Murphy, of the Huerfano Coal Co.; H. F. Nash, of the Oakdale Coal Co.; J. J. Roche, of the Rocky Mountain Fuel Co.; J. van Houten, of the St. Louis, Rocky Mountain & Pacific Co.; J. F. Welborn, of the Colorado Fuel & Iron Co., and F. R. Wood, of the Temple Fuel Co.

## Coming Meetings

**First International Management Congress**, Prague, Czechoslovakia, July 21-24.

**Western Canada Fuel Association**, Convention Aug. 5 and 6, 1924, Brandon, Manitoba, Can. Secretary, W. H. Morrison, Winnipeg, Man., Can.

**Rocky Mountain Coal Mining Institute**, Summer meeting, Aug. 7-9, Rock Springs, Wyo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

**New York State Coal Merchants Association, Inc.**, 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

**Oklahoma Coal Operators' Association**, Annual meeting Sept. 11, 1924, McAlester, Okla. Secretary, A. C. Casey, McAlester, Okla.

**Association of Iron and Steel Electrical Engineers**, Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

**National Safety Council**, Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers**, Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers**, Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Ball Bearings a Feature of Pneumatic Grinder

A pneumatic motor for operating portable drilling and other tools and designed to meet exacting requirements, and a new portable pneumatic grinding machine have been placed on the market by the Cleveland Pneumatic Tool Co., Cleveland. The outstanding feature of both the motor and the grinding machine is that both are provided with ball bearings.

The pneumatic motor is made in plain and compound-gear types. It is a four-cylinder unit having four single-acting pistons connected to opposite wrists of a double-throw crank. These wrists are grooved, hardened and ground, forming an inner ball race. The four connecting rods are enlarged at their end into a ring of sufficient size to be hung on to the end of the crank. The inside of the ring is machined to form the outer ball race. After the connecting rods are placed in position on the crank the balls are inserted and are retained in position by a spring ring retainer.

The pistons are screwed to the piston sockets, which in turn are attached to the connecting rods by a floating wrist pin which has oil holes for lubrication. The main valves are of the solid piston type and are operated from eccentrics on the crankshaft. They are placed between each set of cylinders from which they are separated only by a thin wall in which air ports are provided. The live air is, therefore, injected almost instantly into the piston chamber, assuring, it is claimed, quick motor action and conserving air. It is stated that on account of the reduction in friction through the use of ball bearings and the added power gained through quick delivery of the air to the pistons a very high motor speed and high drilling capacity is obtained.

The bearings on the crank and connecting rods, as well as the rods and pistons, run in the lubricant and the

**Compact Pneumatic Motor**

Equipped with four single-acting pistons and ball bearings this little air motor is claimed to be highly efficient and easy to maintain.

gears are similarly lubricated. The gear chambers open directly into the crank case, which is filled with an oil and is so constructed that the lubricant is not driven out when the motor is in action.

The portable pneumatic grinding machine has an arbor or extension covered by a housing which is used as a forward handle. The arbor is connected directly to the crank as shown in the illustration, and is mounted on annular ball bearings at both ends, as is also the driving crank. The single-piece connecting rods contain ball races, which operate directly on the crank. These races as well as the annular ball bearings on the crank and arbor bearings have continuous lubrication both in the crank chamber and in the forward quill housing. All the revolving parts run in lubricant.

The body is split at the center, which permits the removal of the crank assembly without disconnecting the pistons or valves from the crank. The piston cups are screwed to the piston sockets and reinforced by a lock nut at the base of each cup. The connect-

**Portable Grinding Machine**

A shield protecting the emery wheel makes it safe to operate this machine in close quarters. The lubricating system is arranged to supply oil to all wearing parts regardless of the position in which the outfit may be turned.

ing rods are attached to the piston sockets by a floating wrist pin, which is perforated for lubrication. Four types of throttle handles are available, these being the inclosed type with outside or inside throttle levers, a straight handle with snap throttle lever and a straight handle with twist throttle sleeve. The machine is made in two sizes, one weighing 12 lb. having a 6-in. emery wheel and a speed of 4,600 r.p.m., and the other weighing 21 lb. having an 8- or 10-in. emery wheel and a speed of 3,600 r.p.m.

## Portable Coal Loader

With its positive, self-feeding device the new path-digging loader recently announced by the George Haiss Manufacturing Co. will load any kind of anthracite or bituminous coal, from lumpy run-of-mine to buckwheat. The feeding propellers do all the work, and the only labor required is that of the one operator. There is no shoveling. The machine is provided with a slow-speed crowding gear which can be brought into play simultaneously with the combined loading action of the buckets and self-feeding device. This keeps the machine fed up against the pile in its most efficient working position, and, with the revolving propellers, digs a path right into the pile.

The self-feeding propellers are twelve slanting vanes, extending to each end of the shaft at the bottom end of the elevator. These rotate slowly under power and move coal gently and automatically from the out-

side one of the series, successively to the inner one, which delivers it in front of the loader. The buckets are heaped full continuously and discharge a full load into the truck.

The propelling mechanism is connected from the driving unit by a chain to a countershaft, then through a clutch to a jack-shaft, and thence to the two rear traction wheels by means of pinions and gears. The main gear shifter controls one forward and one reverse motion of the loader. The loader travels backward 60 ft. and forward 100 ft. per minute. A second, or very slow-speed gear-shifter engages a worm drive which propels the entire machine backward at a speed of only 30 in. per minute, while the feeding propellers convey the material to the buckets.

The wheels have a 10-in. face, and the driving pair are furnished with traction cleats. Heavy steel-plate propeller blades are bolted on to extra large cast-steel lugs which in turn fit rigidly on the big steel propeller shaft.

**Power-Driven Self-Feeding Coal Loader**

Propeller blades on the sides of the elevator buckets dig into the pile and pass the coal from the sides to the middle where the buckets are filled. A slow-speed crowding gear simultaneously keeps the loader well up against the pile so that the buckets are always full.

The revolving speed of the feeding propeller and the pitch and number of the blades, conform with the speed and the capacity of the elevator buckets. The spread of the feeding propellers across the back of the loader is more than the over-all width of the loader.

The construction is all-steel. The elevator truss frame is pivoted at the center and can be collapsed when moving the machine under overhead obstructions. The front wheels are 24 x 10 in. and have roller bearings. All other turning parts have bronze bushings. The machine bearings are provided with grease cups and the motor bearings have oil reservoirs.

The front axle is similar in design to that on an auto truck. The axle does not turn when steering the machine, but instead the two front wheels are steered by a handwheel through a worm and sector device and steering knuckles.

## Hand-Fastened Trolley Clamp With Aligning Feature

A new aligning clamp so constructed that it may be installed without any strain on the insulation of the hanger is just announced by The Ohio Brass Co.

This clamp is practically identical in appearance and construction to the

**Aligning Type Trolley Clamp**

This device may be aligned on the hanger without being loose on the stud or disturbing the insulation. Little labor is required to install the clamp and suspend the trolley wire.

Bulldog clamp except that it has the aligning feature. It has the same self-opening jaws that are controlled by the nut both when being opened and closed.

The new clamp, like the ordinary clamp of the Ohio Brass Co. without the aligning feature, is tightened onto the hanger stud by gripping the jaws with the hand. This is unlike usual types which cannot be tightened onto the hanger stud without applying a wrench to the nut. This difference is due to the fact that the jaws are loose on the boss for only slightly over one-half turn instead of being altogether loose. One-half a turn is sufficient to back off the jaws to align with the trolley wire after the clamp is tight on the hanger stud.

Tightening of the jaws on the wire with the nut does not affect the hold on the hanger as the nut itself does not touch the hanger insulation. There is no pressure against the insulation nor any grinding or wedging action.

## Now It Can Be Told

THE WAY may be clear for coal trade statistical reports once more. At least it appears to be. Harlan Stone, United States attorney general, has shown no desire to upset the business advancement plans of the Department of Commerce as Harry M. Daugherty did before that gentleman was oiled out of the cabinet. And since the best information on the subject leads the Hardwood Manufacturers' Institute to believe that Mr. Stone is going to take the same sound position that Secretary Hoover of the Department of Commerce takes in encouraging trade statistics, it is preparing to resume the issuance of sales and stock reports. So the way appears equally open for the exchange and publication of data on closed transactions in coal.

With the coal market in its present deflated condition it is hard for some coal men to see what good it will do them to receive such data. There is so little trading in coal that everybody knows all about it without statistical reports—so they say. Nowadays the sale of one hundred tons of mine run creates almost as much furore among coal salesmen as a circus parade does in a townful of “kids.” But even in such a condition, the coal market would be more stabilized and less ruled by rumor if every legitimate trader in it knew positively what every other legitimate trader did the day before. And times are bound to change. People simply must begin buying coal before long. When they do the need for straight statistics on coal markets will be keener. The time for coal trade associations to get back on their feet and organize for service is now.

## Another Crime Averted

SOME of the gas journals, says G. S. Brewer in his report to the City of Buffalo on its fuel problem, want gas made at the mines. Later he proceeds to declare that the pipe should have a capacity one and two-thirds times as large as the average needs, so as to take care of the peak load.

We who have learned that our industry should be so regulated that it would have no excess capacity but always be just what the need demands or that we should regulate demand so that it would always fit capacity are surprised at this suggestion. Has Mr. Brewer no imagination or sense of leadership that he cannot find a way short of providing a pipe of excess capacity? Could not gas of a higher thermal equivalent be made in the winter? Could not the pressure of the gas pumps be increased when the cold winds blow? Could not the pipe be made to expand when the demand was greater? Could we not attempt even a revision of Boyle's law? Anything but an excess capacity!

But then if the gas were made of a high thermal value, the gas pressure were increased, the pipe ex-

panded, or Boyle's law were conveniently modified, why not use these magic powers all the year round? A smaller investment would then suffice, but there would still be that excess capacity. How prodigal! It is well the crime was averted, that G. S. Brewer nailed the sinful waste within the four narrow walls of his conclusions so tight that no one can hear its groanings, for had he not done so the coal industry, hoary with crime already, would have sinned again. No more excess capacities! An excess capacity in mines and men is enough; no excess capacity in pipes, in gas, in gas pumps should be added to the many offenses of the coal industry.

## Illinois Gets a Loader Scale

MACHINE loading of coal underground is free to go forward in Illinois at last. The scale for operators of loading machines which has just been signed by the Chicago, Wilmington & Franklin Coal Co. and its employees is not state-wide but it might as well be. It is the die in which all future wage agreements for machine operation probably will be cast, as company after company installs loading machines. The most agreeable thing about it is that it puts machine loading on a per diem instead of a tonnage basis—and that in the citadel of unionism, Illinois!

There is no controverting the fact that the coal-loading machine logically should be operated at present by men paid a flat daily wage. The volume of work a certain type of machine will do in eight hours under given mine conditions largely is determined in advance. If the operators do not bring it up to that capacity, they are not giving the machine or its owners a square deal. They certainly cannot push it beyond its limit no matter what their skill or willingness. Therefore, machine loading is not piece work in the nature of it and we are glad the Chicago, Wilmington & Franklin Coal Co. has established this wholesome fact in its agreement. Such an agreement couldn't have been written with John Lewis' union a month earlier than this one was.

The job that now confronts that coal company and every other company that adopts machine loading in Illinois is the ever-present job of getting a full day's work out of men paid on that basis. It is reasonable that intelligent and industrious Illinois machine loader runners receive \$10.07 for a full day of eight hours with a loader such as those on the market now. But that is a big day's wage, judged by any sound standard of manual labor. It now remains to be seen whether such a wage will attract, as has been frequently predicted, a class of high grade, square-shooting miners who will realize this fact. If it does, then the cost of producing coal in machine loading mines will be sufficiently reduced so that those mines will get business and the miners in them will get work.

## Are More Miners Needed?

DESPITE public clamor the cry still persists that coal loaders are scarce. A few years ago this cry was somewhat general. It has been only stilled, and that partly, by declarations from high authorities that there were altogether too many men for the tonnage the country could absorb and that this was true even at times when the demand for coal was greater than could be supplied from the coal fields owing to lack of transportation facilities.

No one can deny that this is true, yet the need for more men is still one of the perplexities that trouble operating officials. The reason for the paradox is the excessive number of mines in the coal fields. Almost every operator could find places for more men, and nearly every mine owner knows that if he had a larger force he could produce cheaper coal. So the hunt for men continues. Whether this is advantageous to the country as a whole is questionable, but it is natural for every owner of a coal mine to seek to hire as many men as will make operation profitable.

Certain parts of the country are more clamorous than others. The anthracite region is one of these. The law in that region requiring that every miner must have served for two years as a laborer under another miner has unduly restricted the supply of men. As anthracite is greatly needed the demand of that region is accepted as reasonable and as a problem in which the consuming public shares.

Another region is West Virginia. At first it met its demand by drawing on the farming population, which readily left its unprofitable farms on the steep hill-sides for a more profitable occupation in the mines. But West Virginia was sparsely settled. Much of it was unfitted for the plow, and the market being remote, the population had not been supplemented by immigration. In consequence of the lack of native labor, West Virginia made a heavy bid for alien immigration to support its growing production, alleging, however, that the Department of Labor favored union regions and directed the new arrivals away from non-union fields.

Consequently West Virginia has felt the lack of labor more perhaps than any other coal-producing region. Its call for labor has always been insistent. Its lack of miners has kept it from the development that its nearness to the sea coast, its low freight rates, its excellent coal, the spread of its coal fields and its lower daily wage rates otherwise would have afforded it. Some of the other coal areas have not been greatly sympathetic with this lack of labor, but it naturally has been a thorn in the flesh of West Virginians who are interested in the progress of the state.

Now the state has been further hit by the restriction of immigration, which possibly bears more heavily on mining than on other industries. Progress in West Virginia is retarded. The public, however, is so strongly convinced that there are too many miners that it will be a long time in doubt whether ameliorative action should be applied.

Those who wish to see the miners kept steadily working will not be sorry to learn that forces are at work to reduce the mining population. The miners also will rejoice. It may be only a few years before the operation of conditions such as are described in an article appearing in this issue and entitled "Coal Loaders—How Are We Going to Get Them?" may bring the number of miners down to such a level that their output

—greatly augmented by machinery—will be sufficient only when working steadily to supply the market. Then may come a condition the converse of that now existing. Meantime and thereafter West Virginia will suffer and coal-loading machines and conveyors will have a day of rapid extension.

---

## Watching the Parade

THOUGH coal never leads the country's industrial parade, it never gets left around the corner, either. It always keeps up in the long run with the rest of the procession. Therefore, when the coal industry marks time it does the coal man good to get up on an eminence somewhere and view the rest of the parade—that is, if the result of his observation proves to him that the other paraders are still moving onward with unfaltering step. He knows it will be only a short time till his own contingent is ordered forward on the "double quick." The glance he will make just now will fill him with encouragement. He can hardly pick a better place to look than at the statistics charting the course of revenue freight cars loaded with all commodities, remembering that the country ships goods only when it is busy.

These charts now show that during the first half of 1924 the railroads loaded more revenue freight than during the first half of any year since 1919 excepting last year, and that 1923 was only eight per cent ahead of 1924. The total revenue freight loaded thus far in 1924 is a trifle of twenty-three million cars, which constitutes a briskly moving procession no matter by what standard it may be measured. Naturally the two-weeks period over the Fourth of July shows a drop, as ever, but the rebound also occurs, as usual, and loadings are now on their way upward toward the inevitable fall peak. This 1924 is well on its way toward the fifty-million mark which 1923 established in revenue car loadings.

There is something wholesome about this industrial parade of freight cars up and down and back and forth across the United States. It indicates that the country's huge stock of coal is swiftly going down. In spite of the fact that coal loadings, which normally represent a third of the country's freight movement, are about 40,000 cars a week under 1923, the carriers are otherwise busy and there is no denying it. There is no confusion about their activity, however, for never in the recent history of railroads have they been in such good shape mechanically and in personnel. But they are handling a vast volume of freight. And coal loadings are moving up at about 3,000 cars a week.

The main question of interest to the coal man, as he takes this glimpse at the freight parade is: How fast will this acceleration of coal loadings proceed? When will they be up to "normal"? It is true that iron and steel production is low and has been dropping since March. It is true that production in some other lines, notably automobiles, continues low. But it also is true that average consumption of commodities generally has taken its upward turn and is now ahead of output. This naturally will soon cause a turn in production.

So, in spite of this being presidential year, there is little inflation and general economic conditions are sound. A steady upward trend in coal consumption is already starting. The country's industrial parade is headed in the right direction.

# Suggestions for Concentrated Machine Mining

Coal Is Produced by Manual Labor, Every Other Commodity by Machine—Mines Laid Out to Suit Hand Methods Not Adopted to Machine Loading—Conveyors Greatly Simplify Machine Operation

BY N. D. LEVIN  
Columbus, Ohio

WE LIVE in an age of machinery; almost everything by which we satisfy our daily needs is produced by mechanical means. The soil is tilled, the crops harvested and the production of food of every description in sufficient quantity and proper quality is today possible only through the aid of machines. The houses we live in, the furniture with which they are provided, our transportation systems, our telephones, in short practically everything needed, used or consumed by the human race, with one great exception, is produced by machinery. This solitary exception is coal. In many localities this fuel is still mined with pick and shovel and almost the entire output of the country is loaded underground by hand.

Many people have realized this situation and have sought to produce machinery for loading coal in the mine. During the last twenty years many hundreds of patents have been taken out, and millions of dollars have been spent on the development of coal-loading machines. And yet nearly all of the coal produced is loaded by hand. The reason for this is not in the obstacles encountered in developing loading machines, but in the difficulty met with in adapting machines already perfected to mining systems that were developed when nothing more mechanical was available for the purpose of coal production than pick and shovel.

With hand loading, the output from each working place is limited; consequently a great number of working places are needed in each mine in order to obtain the desired output. It is evident that it is not practicable to use machines if they must go into several hundred places in order to obtain the necessary production. There are too many delays of various descriptions

in attempting to load mechanically in such mines, and it is these delays that are responsible for the economic failure of coal loading by machinery.

It is necessary therefore, to change the mining system so that machines can be kept going a full shift in the same working place. Means also must be provided for removing the coal without interruption.

## LOCAL CONDITIONS FIX PLAN TO BE ADOPTED

The object of this article is to suggest certain principles that should be kept in mind in laying out a mine or a part of a mine for mechanical loading. Each locality will have its own problems to solve. It is hoped that the accompanying diagrams may help to suggest some scheme that can be worked out successfully.

Fig. 1 shows the V-system that is being used by the West Virginia Coal & Coke Co. This system of mining was fully described in *Coal Age* (issue of Feb. 7, 1924, p. 197) and needs no further comment here.

Fig. 2 shows a modification of the V-system. Conveyor-loaders are used on the working faces delivering coal into sectional conveyors, which in turn deliver it to a main conveyor. The narrow work is performed by entry-driving machines and sectional conveyors. One loading point serves the entire system.

Fig. 3 shows a system embodying several faces indicated by numbers 2, 3, 4, 5, and 6. These faces may vary in length from 75 to 200 ft. or more, depending upon local conditions. A loading machine and a conveyor, or a combination conveyor-loader serves each face. The coal from face No. 2 is delivered to a conveyor on entry No. 2. That from face No. 3 is delivered to a conveyor on entry No. 3 and so on. These

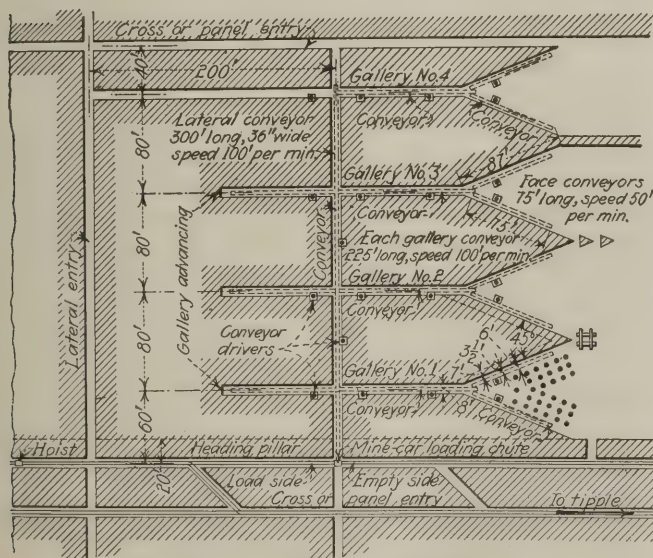

Fig. 1—V-System of Mining

By the arrangement shown each pillar furnishes two faces, each of a length approximately equal to the width of the pillar. A large tonnage is thus secured from a comparatively small area, supervision is concentrated and the advance is rapid.

Fig. 2—V-System of Mining Modified

In the mining system depicted the pillars are worked on long slanting faces. All mining is done by machine and both development and main extraction are performed rapidly. Again, supervision is concentrated and efficient.

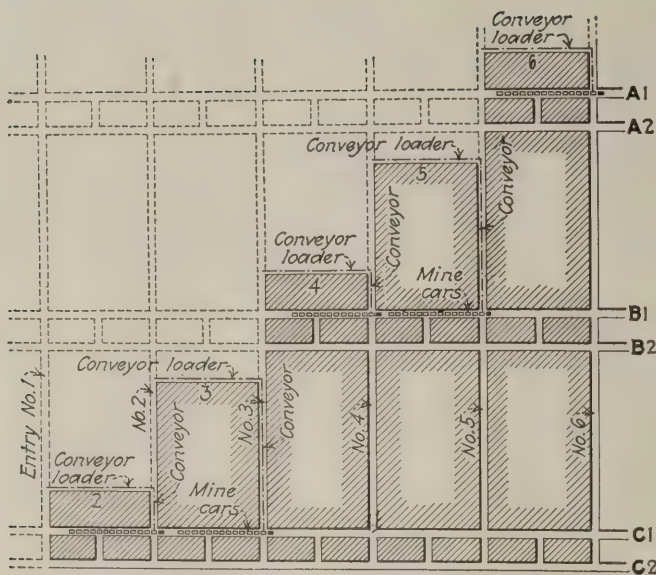

Fig. 3—Panel System, Worked by Conveyor

Five trips of cars are shown loading on three entries at the same time. The faces, which are made of a length to suit conditions, are arranged in echelon so that the line of roof break presents a saw-toothed appearance.

conveyors are made in sections so that they may be shortened as the face is brought back. The coal from faces 2 and 3 is loaded onto cars on entry *C1*, and that from faces 4 and 5 is loaded on entry *B1*. In order to obviate interference between the two loading points on each entry, as they are rather close together for handling long trips, and in order to keep an uninterrupted car supply at each loading point, a certain amount of switching will be necessary between entries *B1* and *B2*, also entries *C1* and *C2*.

It is believed that it would be economical and preferable to provide an additional conveyor for each pair of face entries, as shown in Fig. 4. In this case, the sectional conveyors on entries 2 and 3 deliver coal into a conveyor on entry *C1*, which loads cars on entry No. 4. This arrangement is duplicated throughout the mine. The empty trip may be brought in on entry *C1*, switched through entries Nos. 5 and *B2*, and then to the loading station in entry No. 4, the cars being all loaded at the intersection of entries Nos. 4 and *C1*. This will do away with a gathering locomotive, and one

Fig. 4—Another Conveyor System of Mining

The mine layout is practically the same as in Fig. 3 but more conveyors are used so that coal from two faces instead of one feeds to each loading point. Fewer but perhaps heavier locomotives will accordingly be required.

loading point will serve for two faces. A small rope hoist should be provided near the loading point, so that one man can feed the trip past the discharge end of the conveyor, which is not stopped when shifting cars.

Fig. 5 shows a mining system worked out by the New River Co., MacDonald, W. Va. In this plan a combination conveyor-loader serves face No. 1, and another face No. 2, one machine carrying the coal in a left-handed and the other in a right-handed direction. A sectional conveyor is provided on an entry which divides the face into two parts. Each face will be about 80 ft. long; that is, faces 1 and 2 together will be about 160 ft. in length. One object in driving the extra entry in the middle of the face is to provide a safe retreat for the men in case such a retreat is needed.

Fig. 6 shows the adaptation of a room-and-pillar system to loading machines. Butt entries are shown 600 ft. apart; narrow rooms are driven clear through between these entries. The rooms may be driven 12 or 14 ft. in width by entry-driving machines. The coal is taken away from these machines by means of sectional conveyors that are lengthened as the entry drivers advance. After the rooms are driven through, slabbing cuts are made with either longwall or short-wall machines; the coal is shot down and loaded out by mechanical loaders suited to longwall work, or by combination conveyor-loaders.

If the distance between the entries is 600 ft., each conveyor-loader would serve about a 300-ft. face. The coal is carried to butt entries at each end of the room; that is, carried right and left along the face. On each butt entry is a conveyor that takes the coal away from both the slabbing machines and the entry drivers. Two slabbing machines are shown in this figure as well as two entry-driving machines discharging into a common conveyor, which in turn loads a trip of cars from the side by means of a chute. This loading point will remain at the same place for a considerable time; consequently in many cases it would be entirely practical to take down sufficient top at this point so that the conveyor can be elevated high enough for a chute to be used for loading.

Fig. 7 shows a three-entry system. This may be used where the roof is of such a character that it will not permit of slabbing the rooms entirely out to the entry. In such a case, the crosscuts in the pillar between the middle entry and the room entry act as room necks.

In this layout one conveyor takes the coal from one slabbing and two entry-driving machines. A short conveyor is provided through one of the crosscuts, and the trip of cars is loaded on the center entry.

Fig. 8 is the same as Fig. 7 except that a possible way of drawing pillars is indicated. Under some roof conditions it may be possible to use light portable conveyors to take the coal from the pillar to the slabbing-machine conveyor.

#### MODIFIED ROOM-AND-PILLAR SUITED TO MACHINES

It appears that in practically any mine, the present room-and-pillar system may be modified to suit mechanical loading along some such lines as those suggested. The top can be handled exactly as it is in the present system, and as rooms can be worked out in an exceedingly short time, it is believed that, with the same degree of safety, they could be driven much wider than under present mining methods.

To the left in Fig. 9 are shown two cross-sections of

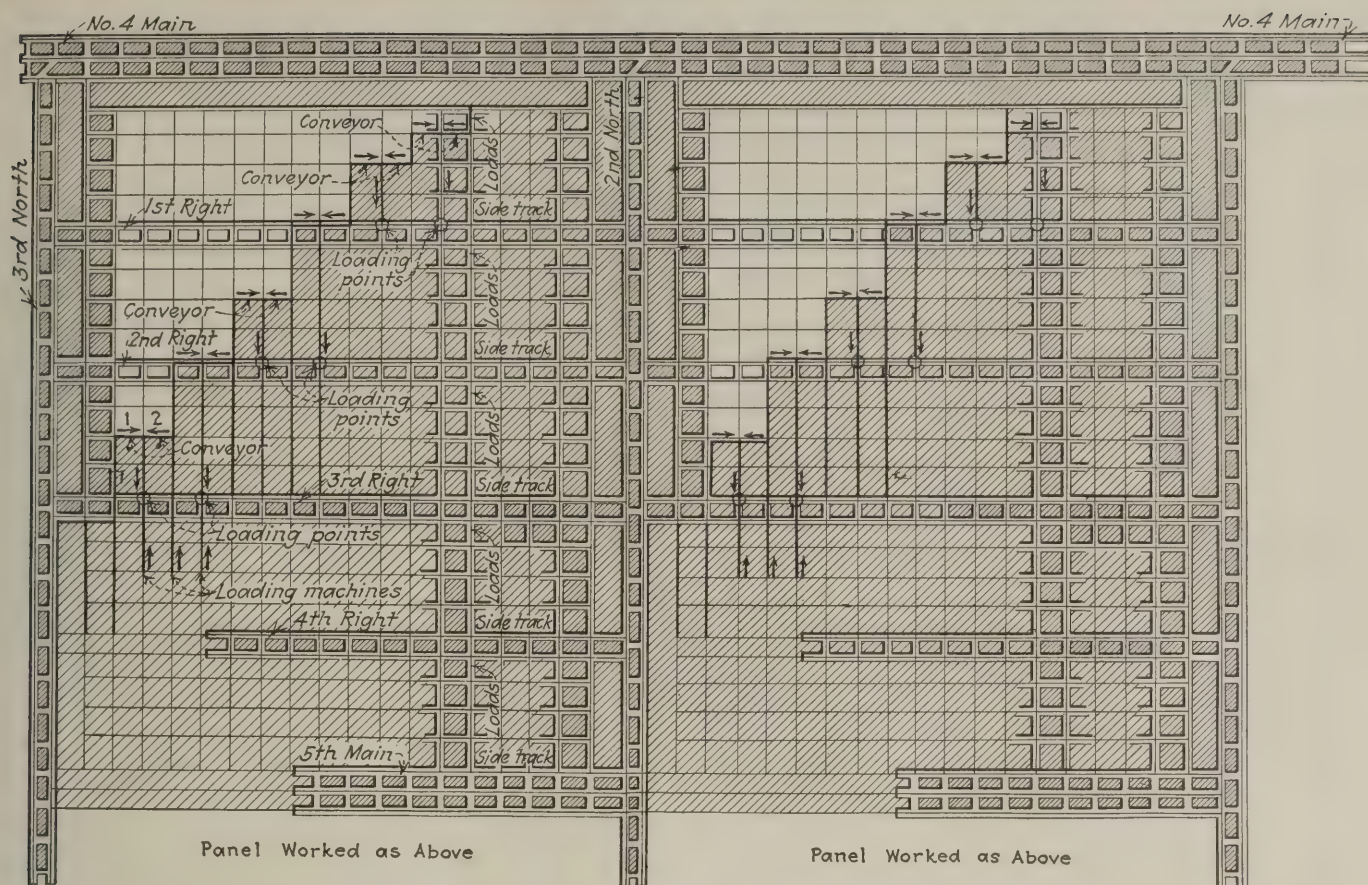

Fig. 5—How the New River Co., of West Virginia Operates the Panel system

Here again two faces are tributary to each loading point. The breakline, as before, is saw-toothed. The rapid advance of the faces obviates the excessive use of timber.

a long face such as those worked in Fig. 4. The upper cross-section shows a longwall machine making the undercut. Behind it is a combination conveyor and loading machine which reaches the entire length of the face. The space between the face and the first row of posts is 6 ft. in width. This gives ample room for both the machine and the conveyor-loader. It is possible to reduce this distance to 5 ft. in case of necessity, but 6 ft. is preferable. The lower left-hand figure shows the coal shot down.

This figure indicates a 7-ft. bed and in such a case, after shooting, the space between posts and face would

be pretty well filled up with coal; consequently the conveyor-loader is covered, before the shots are fired, with short pieces of board which are removed afterward one at a time, beginning at the discharge end, the coal being carried away as the boards are withdrawn. The machine is then fed forward into the pile.

The two sections to the right in this figure show the same arrangement in a thin coal bed. As soon as the coal is loaded out at one end of the face, the setting of a new row of posts can be begun, as the conveyor-loader is flexible and is not moved up into the coal pile bodily, but with the tail end first. The rest of the conveyor is then gradually moved over so that by the

Fig. 6—Room and Pillar Worked by Conveyor

Both entry drivers and conveyor-loaders feed to heading conveyors. Slabbing cuts along the 600-ft. ribs furnish a large tonnage. Some coal, however, is lost in the pillars that cannot be entirely drawn.

Fig. 7—Room and Pillar for Weak Roof

This is a modification of the system shown in Fig. 6, being better suited to a cover that breaks easily. By this plan cars are always protected by the pillars upon either side of the loading entry.

Fig. 8—Drawing the Pillars of Fig. 7

If the nature of the roof is such as to permit the removal of the room pillars, this may be done by means of short conveyors feeding to the conveyor-loaders. Although only two cross-conveyors are shown it is probable that in some cases more could be used to advantage.

time the coal is all loaded out, another row of posts 6 ft. away from the new face has been put in place. The arrangement of mining indicated in Fig. 9 is recommended for any thickness of coal where the roof is bad. The conveyor-loader is only 17 in. high, and the long-wall machine is of about equal height.

Adequate ventilation in mechanically-operated mines is somewhat difficult to provide because of the lack of uniformity in state laws. At the time these various statutes were enacted they were necessary and beneficial, but as the art of mining coal advances, the laws must be altered to take cognizance of modern methods and changed conditions. It would be absurd to compel a railway company in building a tunnel through a hill, to drive two passages with cross tunnels between them, in order to convey air to the men who are working at

Fig. 9—Cross-Sections of Thick and Thin Beds

Thick beds naturally produce more coal than thin ones. In a thick bed as shown at the left it may be necessary to protect the conveyor-loader when shooting the face. The removal of the protecting boards allows much of the coal to roll onto the conveyor-loader by which it is removed. The machine is then fed forward into the pile.

the face. In tunnel driving positive ventilation can be maintained by mechanical means. It should be permissible likewise in coal mines.

For instance, in driving narrow rooms, such as those shown in Fig. 7, a blower should be provided on the butt entry, fitted with a canvas tube reaching up to the face. This tube can either be extended as the machine advances, or, brattice cloth can be employed. This is really a safer procedure and insures a better supply of air than is available by the use of crosscuts. Furthermore, in entry driving it saves stopping up a great number of cross passages. It also effects a considerable saving in the cost of ventilation, as it is difficult to prevent leakage through stoppings.

## Why Fuss with Your Planimeter Scale?

CHANGING the planimeter vernier to suit different scales introduces possibilities of error and takes time. It is better to leave the vernier in place and multiply the result by an appropriate factor.

The accompanying table gives the factors by which planimeter readings must be multiplied when the instrument is set to the equivalent of 1 in. = 100 ft., to convert these readings to acres. This table makes it unnecessary to change the vernier on the planimeter tracer bar when working on plats or maps of different scales. This vernier may be set permanently for a scale of 1 in. = 100 ft. and the instrument operated in the usual way. The reading when multiplied by the factor shown in the table as equivalent to the scale on the map on which work is being done will then be the area in acres.

Suppose that a Coradi planimeter with the tracer bar set at 216.00, equivalent to a scale of 1 in. = 100 ft., is being used on a map the scale of which is 1 in. = 30 poles, and that after tracing a certain area the instrument reading is 0111. The factor shown on the table as being equivalent to the map scale is 0.05625. Accordingly multiplying the instrument reading by the factor we have: 111 × 0.05625 = 62.4375

This is the number of acres in the area traced.

To obtain the proper factor for any map scale not shown (when the planimeter is set for 1 in. = 100 ft. as previously stated) the following formulas may be used:

$$F = (S^2 \div 100) \div 43,560$$

$A = F \times R$ , where  $R$  = reading of instrument,  $S$  = scale of map or plat in feet,  $F$  = the factor and  $A$  = area in acres.

The Type of Families the Mines Are Losing—The Father Once Was a Record Coal Loader, but Today He Lives in Cleveland

The Three Older Boys Now Are in College and Two Are in High School—For These the Coal Mines Must Find Substitutes

## Coal Loaders—Where Are We Going to Get Them?

Education and Non-selective Immigration Are Reducing the Number of Active Coal Loaders in the United States—These Must Be Replaced by Mechanical Loading Machines or Some Other Steps Must Be Taken

BY WILLIAM A. BUTLER  
Charleston, W. Va.

**M**UCH effort has been expended in the education of mine employees. Let us not hope that for any reason the intensive drive for better education and more of it will slacken, no matter how forcibly we may recognize the fact that education is reducing day by day the number of coal loaders in the United States.

I have given this problem particular attention for the last few years and have studied the ideals of the best coal loaders at many mines and not a one of them have I found that expects his son to be a coal loader. He is educating him, training him and pounding into him day after day the necessity of earning his living in some occupation more desirable than coal mining. He shrinks from the very idea of his boy being a miner.

You may canvass a mining town of almost any size from end to end and question the parents of every boy in the place, and I do not believe you will find a single parent that will tell you that they want their boy to be a miner. You may find a few of the newly-arrived foreigners that do not have the higher ideals of Americanism are content to have their sons follow the employment in which they are engaged, but every foreigner who has reared his children in the United States and has placed them in our schools, is going to hope and expect his or her children to be more than coal loaders. Nevertheless, though education is making problems for the coal operator which give him much concern, he can only praise the ambition of these foreign-born citizens and lend them a hand in the elevation of the boys of the coming generation or generations.

It is the unselfish nature of every true American and a trait that I do not doubt will win in the end, for as the old-time miners are diminished, the mechanical loading machine will take their places.

No one will venture to say that the coal operator is selfish in this matter. I have yet to see the operator who

fails to encourage better education, better living and higher ideals. Never have I seen an operator who tried to teach the coming generation the best way to load coal. He may show the present-day loader the best way to perform his task, but he does not offer any such schooling to the coming generation.

In many sections of the country today, the coal operators are paying out much money to promote better schools and to provide more of them. I know of many companies that for the purpose of building good schools, paying a part of the teacher's salary, furnishing janitor service, athletic equipment, etc., are even adding their contribution to the state and country allowance for education. They are determined that the children of their employees shall have the best possible educational advantages.

### BOY WITH GOOD EDUCATION WILL NOT MINE COAL

They know the boy that gets a good education is not going back in the mine to load coal; they realize that the boy that finishes high school and goes to college is not likely to remain in their organization, yet, they do all in their power to make that boy a finished product. That cannot be called selfishness. It is rather an exhibit of unadulterated Americanism. However, it is reducing the number of active miners in the United States and that fact cannot be denied.

Every year, hundreds of miners are drifting from coal loading into other industries on account of the irregularity of the business. Owing to poor market, poor car supply, strikes and other causes slack runs are, as we all know, frequent visitors in the coal-mining industry. This fact forces the miner to seek employment in other lines of work, and many of them never return to the mines.

Where are we getting the miners to replace those that are growing too old to load coal? Where are we

going to get the miners to replace those that have bought farms and have given up mining or have moved to the cities and taken up factory work in order to give their children the advantages of attending college? Where are we going to get the miners to replace those that have been absorbed by the automobile industry?

Whence are men coming to replace the miners that have made their little "roll" and left for the old country where they will be considered wealthy? We are not going to get them. We shall have to make machinery take their places. Men are not leaving the cities to go to the mines to learn the business. Few men are going to the mines from the farms. The class of immigration we are getting will not fill the vacuity, so where can we turn? Either to machinery, or to better immigration laws.

A survey of the number of miners in the United States today would show enough to supply every demand if they were active miners, but when you go into an employment office to recruit miners you will find that about 75 per cent of these men will try to obtain almost any other kind of employment before they will accept coal loading, and if they are unable to obtain any other kind, some of them then take loading as their last resort; but just as soon as they are able to locate other employment they throw down the shovel and bid the mine *adios* unless they are forced back to the mines by slack work in the factories. You can not possibly class these men as dependable miners. They cannot be relied upon to be at the mines when they are most needed.

We are getting a few miners from Mexico, and according to W. L. M. King, Premier of Canada, some are coming from the Dominion, but, all these combined will not begin to supply even a part of the leakage caused by any one of the sources just mentioned.

Within the past four months, I have interviewed approximately 10,000 men, and I think I would be safe in saying that, though at least 40 per cent of these men have been experienced miners in the past and have followed that line of work all their lives, only about 3½ per cent of them accept positions as coal loaders. In the particular section where I have been located, business has been a little slack along other lines during the past few months, and the employment agent had nothing else to offer them, so the other 96½ per cent walked away unemployed.

It could not be said that this was because the mines to which they were to be transported were undesirable; on the contrary they were among the best in the country and consisted of about forty different mines in different sections belonging to several different companies and operated under various systems. Almost all these men were willing to accept positions near some city that would only pay approximately 70 per cent as much as the mines offered and in most instances the living in the mining region was much cheaper.

It seems that since the signing of the Armistice, men have acquired the city and automobile craze, and it's not only the miners—we've all got it. I know one large coal corporation that during the past few years has had much trouble with this lust for city life.

Their men would make a little stake and go to the cities to blow it in. When their money was spent they would apply to an employment office which they knew represented the company, and the employment office would then have to wire back to the company to know if "John Doe" was a good man, and if it would be satisfactory to ship him back.

This caused so much trouble that the company started issuing what are known as "Identification Certificates" to men who are leaving to "spend their wad" and have made a good record with the company. These certificates certify that the man has been a loyal employee and that the company will be pleased to have any representative employment office advance him fare back to the mines if he applies for it. The certificate shows at which mine he was employed and has a list of plants of the corporation. It must be signed by the superintendent under whom he has been employed and countersigned by the general superintendent or director of personnel. On the reverse side is a list of employment offices throughout the country which represent the company. It is an extended list, for the company has arranged to have employment representation in almost every section of the eastern part of the United States. These certificates are issued in a nice leather card-case of neat appearance.

It is not necessary to call your attention to the fact

that the whole world has gone automobile crazy, but I want to relate a little experience I witnessed recently. A certain coal company gave a newspaper an advertisement which should have read: Wanted—Five first-class trackmen. The paper in printing the advertisement made a typographical error and the advertisement read: Wanted—Five first-class truckmen.

This one little *u* instead of *a* in the word "trackmen" brought in 150 applications within 24 hours. Some of the applicants were experienced, some partly experienced and many of them wanted to know if it would be possible for an inexperienced man to get on that job. The "ad" was promptly corrected and ran for three days and one trackman was employed.

This was not a case of there being lots of "truck" drivers and no trackman, for many of the men that applied for the truck job professed to be first-class trackmen, but did not want the position, but would take the truck driving in preference, about which in most cases they knew little. Truck drivers in that section were getting \$4 a day and the trackmen were offered \$6.80. This is only one of many similar instances I have witnessed in the past year or two.

#### WILL MECHANICAL LOADERS BE PERFECTED?

I know one mining district, where even though the roads have been almost impassable most of the year, recent statistics show more cars per capita than in any other place in the United States.

I believe, as I previously stated, that some day the mechanical loader will supplant the present man power, but the supply of experienced coal miners is diminishing faster than the coal-loading machine is progressing, keeping in mind the practicability of the mechanical loader in all kinds of coal beds.

**C**ANADA will take only such immigrants as she wants. We take whatever offers. In Warsaw applications were filed by twice as many women as men. Only 3 per cent paid their own steamship passage. Dressmakers, tailors, seamstresses, shoemakers and clerks formed 87 per cent of the skilled applicants.

It seems as though something will have to be done to tide us over the period until such machines have been developed. The perfecting of this equipment will take many years, but the time is coming when the mechanical loader will be considered just as essential as the cutting machine and locomotive of today.

Several loading machines are already on the market that have proved to be fairly successful in seams of coal where conditions are good, but these ideal mines are being worked out day after day, and a machine must be designed that will be adaptable to mines having less favorable conditions.

#### SEVERAL MACHINES ON THE MARKET NOW

The Joy digging and loading machine, the Myers-Whaley shovel, the Holmstead loading machine, the Dillig Tractor Loader, the Jeffrey Heading Machine and several others have given fair results under favorable conditions. But when we say they are not adopted to all operating conditions, we must remember that the first cutting machines were satisfactory only where conditions were favorable, but now can be used in any kind of coal from a 2-ft. seam up. Today, they can cut the coal on the bottom, in the middle or the top.

In summing up the problem I have only one way out and that is through proper immigration laws. In thus speaking, I don't mean for a minute that we should open up a flow of immigration that would flood our country with unskilled people, for we are having too much of that now and to do anything that would bring more unskilled labor to the United States at this time, and skilled labor that is not needed, would be one of the worst things that could happen to the country from a labor standpoint.

Neither do I think it necessary to increase the present quota of 2 per cent, but I do mean that we should have immigration laws that will regulate this 2 per cent to a restrictive and selective process, permitting only the classes of immigration that are actually needed for the good of our own nation, instead of admitting men that happen to be able to speak forty words in English and can pass the physical examination.

#### CANADA'S RESTRICTIVE AND SELECTIVE SYSTEM

For some time Canada has had restrictive and selective immigration laws in operation, and Canadians are well pleased with results obtainable. Their system is not based on a quota. It excludes the classes of immigration that are not needed, and until the demand is filled places no limit on the number of any one class admitted.

Section 38 of Canada's Immigration Law almost completely covers this part of their immigration system and gives a good idea of the manner in which it is handled. I quote this section in its entirety. It reads:

The Governor in Council may by proclamation or order, whenever he deems it necessary or expedient: A—Prohibit the landing in Canada or at any specified port of entry in Canada otherwise than by continuous journey from the country of which he is a native or naturalized citizen, and upon a through ticket purchased in that country, or prepaid in Canada. B—Prohibit the landing in Canada of passengers brought to Canada by any transportation company which neglects to comply with the provisions of this act. C—Prohibit or limit in number for a stated period or permanently the landing at any specified port or ports of entry in Canada, or immigration of any specified class or occupation by reason of any economic, industrial or other condition temporarily existing in Canada, or because such immigrants are deemed unsuitable having regard to the climatic, industrial, social, educational, labor or other conditions or requirements of Canada, or because such immigrants are deemed undesirable owing to their peculiar customs, habits, modes of life and methods of holding property, and because of their probable inability to become readily assimilated or to assume the duties and responsibilities of Canadian citizenship within a reasonable time after their entry.

Summed up, Canada's arguments on immigration law stand like this, according to an article recently published on the subject: "Canada's policy on immigration is conditioned by her own needs. At the present these are the development of her vast agricultural resources, for her prosperity along other lines is contingent upon agriculture. In consequence she wants immigrants of the settler type, nation builders. She actively seeks and goes after settlers of this sturdy nation-building type. She reserves to herself the right of a sovereign government to restrict immigration and to exclude those whom she cannot absorb or who do not fit into her needs."

At the time she was in need of settlers only, only settlers were permitted to enter her ports of entry, and this class of immigration the government actually sought. It advertised in over 4,000 magazines in an effort to attract this class of immigrants. However, the true character of this restrictive system of immigration was not apprehended by everyone interested, for after the fiscal year 1920-1921, when the system was put into effect, 30 per cent of the immigrants arriving at Canadian ports of entry were rejected and in the year 1921-22, 39 per cent were rejected.

This, of course, had a tendency to frighten away the class of immigrants the Dominion really wanted. Besides that, it caused much inconvenience to the would-be immigrant, and it was necessary for Canada to take steps to prevent the rejection of immigrants after they had reached the Canadian borders. So, agents with discretionary powers were placed at Antwerp, Paris, Riga and Poland, and more will be placed at other ports soon, to check and sign all passports, and the Canadian companies were instructed to transport only those that had their passports signed by these agents.

#### WE GET WHAT THE OTHERS DON'T WANT

It is far from my desire to take you into a long list of statistics but I do want you to take a glance at what we are getting through our ports of entry. From July 1, 1922, to June 30 of the following year, 522,919 immigrant aliens were admitted to the United States. In the past two years I do not believe many industries could reasonably claim a shortage of common labor and yet out of the above number 275,137 were registered as common laborers and people with no trades, whereas only 5,423 miners were in the total and during that period 803 miners left this country.

Statistics show we have had a scarcity of masons but out of this half million people only 3,276 were masons and 181 masons left. From July to September, 1923, a short period, that being the last date of which figures are available, as the current year's compilations have not been completed, there were 263,259 immigrant aliens admitted to the United States and 136,683 of these were common laborers and people without trades thrown on to our labor market and only 3,035 of this quarter million were miners.

When the American consulate in Warsaw was filling the quota for 1923-24 it requested applicants for visas to fill out questionnaires; from which the following information was obtained: From more than 18,000 applicants for American visas in Poland, nearly 12,000 were women and a little more than 6,000 were men. Only 519 paid their own steamship passages, so that the passages of 17,500 were paid by relatives and friends in America. About 14,000 were unmarried. I have not heard of any distress signal being broad-

casted for barbers, tailors, shoemakers, etc., but we quote in Table I the occupation of most of these applicants:

Table I—Classes of Would-Be Immigrants to United States

UNSKILLED		SKILLED	
No occupations given.....	9,500	Dressmakers.....	810
Domestics.....	2,500	Tailors.....	573
Farm labor, merchants, etc....	2,208	Seamstresses.....	408
		Shoemakers.....	316
		Clerks.....	184
		Bakers.....	154
		Barbers.....	131
		Engineers.....	13
		Masons.....	17
		Miners.....	6
		Paperhangers.....	4
		Plasterers.....	5
		Plumbers.....	5

These figures reveal facts that are worthy of serious consideration. They show what a small percentage of the immigrant aliens being admitted to the United States are really needed and the large number that are not needed, but must be cared for once they are admitted. Industrial reports show that we have a scarcity of engineers, masons, plasterers and plumbers. Sum up these and see how much relief was obtained along this line from over 18,000 immigrants. Look over this list and I believe anyone will agree that such unrestricted immigration is more of a burden than relief.

James B. Howard, President of the National Transportation Institute, said at the recent convention of the American Farm Bureau Federation at Chicago:

## The Miner's Torch

### Questionnaire for the Hasty

**S**UPPOSE you were a company superintendent hooked up to a wife who felt competent to pass on your camp's requirements in welfare and social-service work and furthermore this same wife happened to be the kind of a wife who was not satisfied with simply knowing what ought to be done.

Now suppose that without warning and without request on your part comes a trained social-service worker from the general office of the company who looks over the situation and within a day or two informs you that all of your efforts have been wasted and suggests furthermore a complete change of activities and requests modestly a free hand to proceed without interference. And to back up the notion certain notices are suggested for display so that everyone may be properly informed as to the newcomer's position and authority.

What would you do about it?

Suppose you were a company engineer and unexpectedly a man should walk into your office bringing a letter of introduction from the general manager of your company stating that the company had given an option on its property to another concern represented by the bearer (a mining engineer instructed to make a complete inspection of the company's property) his findings and recommendations to be taken as final. And suppose further that you knew that if you gave this man, sent to inspect the property, all of the facts in your possession, explaining the whys and wherefores of all of the funny looking crooked entries on the mine maps and the

"Unless something is done about the immigration laws to bring more farmers into this country, other countries will soon have all of America's farm products' export trade as the immigration laws are restricting the development of farming to such an extent that other countries are offering better asylums for the crowded-out Europeans, and big colonies are developing large areas in South America as well as in Canada, Australia, Africa and Mexico."

We should find out what we really need, then go after it. We should fill our quota with the class of immigrants that will mean prosperity to the United States, instead of bringing in a class of workmen that will be a source of difficulty to our government in trying to care for them.

A report just made public by the Department of Immigration and Colonization of the Dominion of Canada says that since 1901 Canada has received 3,739,749 settlers, most of whom settled on farms in Western Canada. Of these 1,417,860 migrated from the United States, 1,396,609 from the United Kingdom and 925,278 from other countries of the world.

Are we going to continue to take the riff-raff and rabble of the world to raise, educate and elevate at the expense of our nation's industrial efficiency, or are we going to select and restrict until we have succeeded in placing and organizing those less desirable immigrants who already are within our domain?

blank spaces also, the deal would be sure to fall through.

What would you do about it?

Suppose you were a mining town preacher with a large family dependent on you for support and this support came to you through the route of monthly collections received by the treasurer of your church in payment of pledges made by the members at an annual meeting of the church fathers. The source of these subscriptions would probably be divided about as follows: One-third from bosses, office men, superintendent, etc., while the other two-thirds would come from miners and day men. Suppose further that the church treasurer happened to be the chief clerk in the superintendent's office. (In passing I might state that this last supposition does not require any wild stretch of the imagination). And continuing the supposition, suppose that one fine day out of a clear sky you should discover that the company officials were not giving their employees exactly a square deal; and yet the employees were not aware of the attitude of the officials toward them and their interests.

What would you do about it?

Or reverse the above and suppose that you discovered that the men were not giving their officials whole-hearted support on a matter that had been agreed between them, which fact had not yet been discovered by the employers. (I might add that judging from my experience the first supposition happens seldom, while the second happens a little oftener than seldom.)

What would you do about it?

CARLISLE SPEDDING, prior to taking charge at Whitehaven, England, disguised himself as a hewer and worked in a Newcastle mine. Burned by firedamp, his identity was disclosed and he returned to Whitehaven to originate the "coursing of air" and, in 1750, the "steel mill."

Main-Conveyor Drive and Control Panel, Baker Breaker

## Baker Electric Plant Guarded Against Breakdown

Two Circuits of Over Four-Thousand Volt Current Supply Breaker—Provisions to Keep Equipment from Dust—Impellers for Twenty-Foot Lift at Jigs Designed so as to Prevent Slate in Water from Wearing Pump Parts

BY EDGAR J. GEALY

Electrical Editor, *Coal Age*, New York, N. Y.

**A**LMOST every possible means to provide continuity of service, safe operation and efficient use of power, were incorporated in the plans for the new Baker colliery. The coal now being prepared at this colliery comes from two other mines, the Dodge and National, which originally prepared their own coal.

Although these mines did not have completely electrified breakers their output was mined and transported by electricity. A delay to operation at the Baker colliery is therefore more serious than at other collieries which merely prepare their own output. The electrical equipment of the Baker colliery has been designed to handle the full 4,000-ton capacity of the breaker and like many other breakers will actually handle twice this amount if the flow of coal to the breaker is fast enough.

Two 4,150-volt feeder lines supply electrical energy from the Hampton power plant to the Baker colliery. One of these lines is called the Baker-Dodge-National circuit because it supplies power to each of these places. The other line runs over a different route from the power plant directly and therefore provides a duplicate circuit. Either of these circuits will carry the total load in an emergency.

The Baker-Dodge-National line runs direct to a point in the old Dodge colliery yard, there it divides and a branch turns off to the National mines. The other circuit runs through the Dodge yard where a tap is taken off to the operations in that vicinity. The main line continues to the Baker colliery where it connects with the other circuit from the power plant.

### FOUR CIRCUITS AT THE NATIONAL MINES

The circuit to the National mines ends at a distributing point consisting of four distributing circuits. One branch supplies a 150-hp. fan motor through three 100-kva. transformers, another goes to three 200-kva. 4,150/440-volt transformers which in turn supply energy to three centrifugal pumps. Two of these pumps

are rated at 1,500 gal. per minute and are driven by 150-hp. motors; the other has a capacity of 3,800 gal. per minute and is driven by a 250-hp. motor. Another circuit enters the mines to supply a 112-hp. hoist motor in the Clark bed.

Outside in a brick building are two rotary converters, one is a 200-kw. unit and the other a 300-kw. machine. Both rotaries supply 275-volt energy to the mine trolley system which is directly connected with the inside trolley system of the Baker, Dodge, Taylor and Holden workings, the last two places being mines adjoining the National and Dodge operations.

The high-voltage system at the old Dodge colliery divides into two branches, one supplies a bank of three 200-kva. transformers which furnishes 440-volt energy to the outside shop, two 75-hp. outside fan motors, and a circuit to the inside of the mines which feeds one 100-hp. synchronous pump motor, one 100-hp. induction-type pump motor and a 30-hp. hoist motor.

A 500-kw. rotary supplies the direct-current equipment, in the Dodge mines and also feeds into a super-power network supplying 275-volt direct-current energy to ten other operations of the company spread over a territory nearly 5 miles in diameter. The equipment directly operated from the Dodge rotary consists primarily of seventeen trolley locomotives, eight track pumps, four 50-hp. coal cutters, one 80-hp. hoist, four conveyors and one air compressor.

The beds being mined in the Dodge section are the Four-Foot, Diamond, Rock, Big, New County and Dunmore No. 2. These are given in the order in which they occur. The Four-Foot bed is nearest the surface and outcrops at a point about half way between the Dodge shaft and Baker colliery. The coal from the Dodge workings is not raised to the surface at the shaft but instead is hoisted to the Four-Foot bed where it is taken on a level grade to the outcrop and then transported over the surface to the dump house at the Baker colliery.

There is still another mine associated with the Baker inside operations. This is the Oxford, more popularly known as the old People's Coal Co. mine. The electric power used here is supplied from a 4,150-volt circuit

NOTE—Fig. A in headpiece shows one of the largest single drives in the Baker breaker. By separating important machinery and having individual drives the hazards of the breaker are lessened. Fig. B shows the control panel for this drive which makes it possible to run the motor in either direction at almost any desired speed. Control equipment located near the motor and the conveyor is used whenever a quick stop is necessary or repairs are being made.

### Large Water Circulating and Pressure Pumps Supply Baker Breaker

A spare pump has been provided for each service. The circulating pumps shown at A have a greater capacity than any other pumps owned by the company. These units supply water to the jigs. The pressure pumps shown at B furnish water for the screens, shakers and pressure lines in the breaker and annex.

running from the Hampton power plant to the company shops and offices in the central part of the city of Scranton. Three 667-kva. transformers supply power to a 4,500-gal. per minute centrifugal pump driven by a 1,000-hp. motor and another 100-hp. pump located inside the mines for emergency purposes. On the outside a three-phase 100-kva. transformer supplies the ventilating fan and hoist motors. A 300-kw. rotary supplies 275-volt direct-current energy to the inside feeders which connect directly with the Baker and Hyde Park mines.

At a large tower near the Baker breaker the two

### Transformers Supplying Power to the Baker Colliery

Two circuits furnish power from the Hampton Plant to these transformers. Either circuit will carry the entire load. Located outside the breaker in a clean place, these units give no trouble, yet they easily can be replaced should an accident occur.

power circuits from the Hampton plant are tied together. Switches have been provided so that the energy can be taken from either line and the other cut off for repairs. The principal circuits from this tower supply the breaker, a fan, boiler house, a hoist, inside equipment and the power-converting substation.

Three 400-kva. transformers step the voltage from 4,150 to 440 volts for a 200-hp. fan and the breaker motors. One 200-kva. three-phase transformer on another circuit supplies an outside slope hoist which hauls the coal from an upper bed to the surface. Another bank of three 400-kva. transformers furnishes energy to a 300-hp. supply shaft hoist and also to the inside pumps which raise the mine water from the Dunmore bed to the breaker reservoir. Two of these pumps are centrifugal units rated to deliver 2,000 gal. per minute. Each pump is driven by a 300-hp. 440-volt motor. On another alternating-current inside circuit are two 75-hp. pumps which are used to assist in gathering water for the sump of the large pumps.

The direct-current voltage used in the mines is supplied from a large brick substation located near the hoisting engine of the main shaft. In this substation there is a 750-kw. motor-generator set and a 500-kw. rotary. The larger unit runs in the day, and the smaller machine is held in reserve. At night the rotary is put in service and thus it is always kept in operating condition.

Like the other direct-current stations in this group of collieries these machines are tied into a common direct-current superpower system. Both of the machines are provided with the usual overload, reverse-current and over-speed devices, which are especially necessary on this inter-connected system.

The direct-current equipment used inside the mines consists of twenty-four trolley locomotives, twenty coal cutters, fifteen track pumps, two air compressors, one car-haul hoist, one 100-hp. pump, one 160-hp. hoist and many electric lamps.

All the motors in the breaker are 440-volt, three-phase, 60-cycle units. They vary in size from a 5-hp.

### How Large Volumes of Water Are Circulated Through the Baker Breaker

The circulating pumps are placed so that the height the water must be raised is merely the slight difference in elevation between the water in the column line and that in the reservoir above the jigs. The pressure pumps are always primed because they are located below the reservoir.

motor on the vacuum heating system to a 300-hp. motor on the main conveyor. Nearly all the motors are of the inclosed type and are fitted with conduit-box connection from which a short piece of flexible conduit extends to the rigid conduit set in concrete. There are thus no exposed conductors.

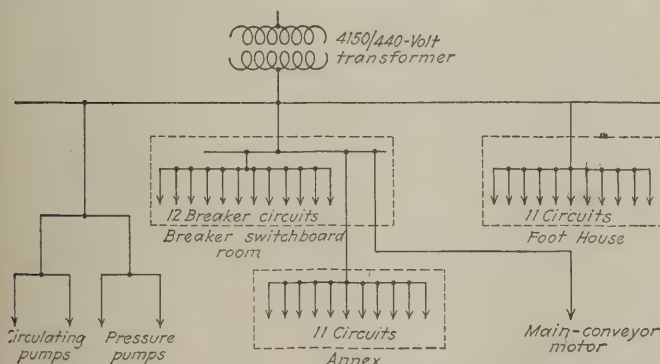

### TO KEEP ELECTRICAL EQUIPMENT FREE OF DUST

So that the electrical equipment will be safe and free from dust many of the motor starters are either hand-operated auto-transformers or push-button automatic starters. The larger motors are equipped with master drum controllers so that the speed may be gradually increased under load or inching can be done while making repairs. Important apparatus driving conveyors, which might under some circumstances cause danger or serious damage, are provided with emergency stop buttons. These control points are provided where they are most convenient. The starters for nearly all the motors are provided with some means for making a quick stop in emergencies.

From a distributing point outside the breaker the 440-volt lines radiate to three different points, one to the foot house, another to the main part of the breaker, and the other to pump rooms.

From an inclosed switchroom in the foot house are eleven different circuits which supply an equal number of motors as follows:

One	25-hp.	Car haul
One	50-hp.	Outside slope conveyor
One	25-hp.	Main shaker
One	35-hp.	Small rolls
One	75-hp.	Main rolls and picking table
One	25-hp.	Rock conveyor
One	75-hp.	Condemned coal conveyor
One	50-hp.	Lip-screen conveyor
One	50-hp.	Rock conveyor from breaker to bridge
One	75-hp.	Rock conveyor on bridge
One	75-hp.	Coal conveyor from pulverizer and lip screen

### How the Breaker Circuits Are Divided

Each motor circuit is doubly protected by relays, switches and fuses located in separate control rooms or near the motors. These control rooms are completely enclosed fireproof compartments. Automatic doors keep these rooms closed off from all other parts of the breaker.

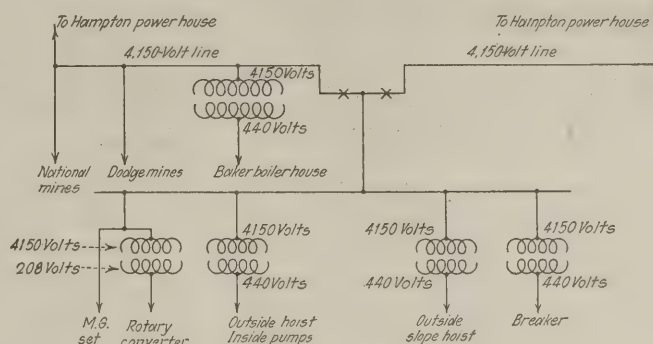

The breaker switchroom circuit is first divided into three parts. One supplies the 300-hp. motor on the main conveyor; another supplies fourteen motors in the annex as follows:

One	75-hp.	Main conveyor from dump
One	100-hp.	Shakers and jigs
One	15-hp.	Conveyor to boiler plant
One	75-hp.	Rock refuse from breaker and annex
One	50-hp.	Rock refuse conveyor feeding the above
One	25-hp.	Annex rolls
One	50-hp.	Conveyor from annex to bridge
Three	75-hp.	Conveyors for fuel to boiler plant
One	50-hp.	Swinging conveyor at dump
Two	50-hp.	Jig pumps
One	5-hp.	Vacuum heating system

The other circuits from the breaker switchroom divide into twelve lines supplying the following motors:

One	25-hp.	Top middle shaker
Four	75-hp.	Twenty-one jigs
One	25-hp.	Settling tank conveyor
One	50-hp.	Top and bottom shaker (north side)
One	25-hp.	Bottom middle shaker
One	50-hp.	Top and bottom shaker (south side)
One	25-hp.	Rock conveyor
Two	75-hp.	Pulverizer

The third circuit entering the building from the outside distributing tower runs direct to the pump rooms. Here are two 200-hp. slip-ring induction motors driv-

### Power Circuits at Baker Colliery

Normally the power supply for the Baker operations is received over two circuits from the Hampton Power Plant. Either circuit is capable of carrying the total load. It is the general practice of the company to use 440-volt motors for nearly all breaker drives.

ing the pressure pumps and two 100-hp. squirrel-cage motors driving the circulating pumps.

The breaker pumping system is quite unusual, every means to prevent loss of water having been provided. The pumps have been located so that they are all self primed. Each unit has been placed where the work it must do is made as small as possible so as to effect every possible saving of labor and power.

The breaker supply or pressure pumps are duplicate units, either one being capable of handling the total requirements. These pumps have a capacity of 300 gal. per minute against a 140-ft. head. The purpose of these pumps is to supply water for the shakers, crushers, lip screens, lip chutes and make-up water for the jigs.

### IMPELLERS OF CENTRIFUGALS SMALL BUT WIDE

The circulating pumps are also duplicate units, each is rated to deliver 14,000 gal. per minute against a 20-ft. head. The impellers of these pumps are of the Francis type and are extremely small diameter but very wide. They were made this way so as to minimize the wear due to the dirt and slate in the water. The low head against which these pumps operate was made possible by locating the pumps directly under the jigs, thus the pump which raises the water into the jig reservoir nowhere circulates it through pipes smaller than 24-in. diameter or to any great height.

### Substation Transformers and Converting Equipment

Here again continuity of service is important and provision has been made for emergency service. During the day the motor-generator set supplies the energy; at night the rotary furnishes the direct-current voltage. Both these machines feed into a small superpower network which interconnects the many coal mines operated by the company. The overhead charges to operate a coal breaker are large; consequently, a continuous supply of energy to the mines is essential for a steady flow of coal through the breaker.

Considering the extremely dirty water handled by the circulating pumps they have given exceptionally good service. The impellers after over a year's service show little or no wear thus justifying the use of the Francis type of impeller.

With every motor clean and free from dust or moisture, all wires in metallic conduits, control apparatus housed in fireproof compartments and all motors pro-

tected against overloads and failure of voltage the work of keeping this model breaker in continuous operation is quite easy for the one electrician employed for this purpose.

Other features have contributed to making this a model breaker but the use of electric power has made it possible to co-ordinate every process entering into the mining, transportation and preparation of the coal.

### Vancouver Fields Unusually Difficult To Work and of Limited Capacity

**PUBLIC** officials and press writers have declared the coal fields of Vancouver Island as "illimitable" and "inexhaustible," but Charles Graham in an address before the British Columbia Division of the Canadian Institute of Mining and Metallurgy shows an entirely different condition to that thus optimistically reported. The results of seventy years of surface prospecting, underground operation and extensive diamond drilling has disclosed the true status of the field.

The presence of coal on the coast of British Columbia first was made known by Dr. W. F. Tolmie in 1835, the mineral being brought to him by Indians from the northeast coast of Vancouver Island, probably from Suquash. In 1850 the existence of coal at Nanaimo was announced by J. W. MacKay. Development started in 1852 and coal was shipped before the close of 1853, the first mines being operated by the Hudson's Bay Co. which they continued to work until 1861 when they sold them to the Vancouver Coal Mining and Land Co.

It is the popular belief that the coal-bearing rocks, known as the Nanaimo series, extend undisturbed from the Sannich peninsula to beyond Campbell river and under the Gulf of Georgia, but geological examination discloses the fact that the coal-bearing rocks are restricted in that area to three principal zones, and that even these zones are not always productive. Further,

throughout a great part of the area only one zone exists, and in the remainder only two of the three are found. Instead, therefore, of the probability of finding coal throughout a zone of rocks over 100 miles long, and covering a large area over the southeast coast of the Island it is now known that the area from which future production must depend is extremely limited.

In Vancouver Island many faulted and barren areas occur when the coal seam is too badly disturbed or too thin to permit of economical operation. In the Comax district, summits of the underlying pre-Cretaceous rocks project through certain parts of the seam. These knobs evidently stood above the general level when deposition was proceeding. They not only form areas of no value in themselves, but have considerable effect on the seam for some considerable distance, and interfere greatly with the general scheme of operations.

Mr. Graham shows that in one mine only 47 per cent of the coal could be recovered and in another the recovery from 365 acres has been to date less than 11 per cent of the coal supposed to be available. In the barren portions of this latter mine the roof and floor meet, completely eliminating the seam; at other points the space between the roof and floor, which naturally should be occupied by the seam is silted up by mud and fine shales. The coal seams are badly intermixed with bands of shale. Whether the coal is shot or loaded without shooting, the shale is brought down and mixes with the coal, making the finer parts of the product exceedingly difficult to clean.

## News Of the Industry

### Interallied Conference Seen as Key to Industrial Prosperity

American Coal Leaders Hopeful of Adjustment of European Situation—  
Steel Corporation's Unfilled Orders Show Extent of General Depres-  
sion—Agriculture's Comeback a Reassuring Development

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Leaders in the coal industry are praying for the success of the Interallied Conference in London. There can be no return of industrial prosperity in the United States, they believe, until the European situation is composed. Stagnation in the coal industry is greater than at any other time in its history. There now is a larger percentage of idle coal-mine capacity than in the latter part of 1914 and early 1915, when the first effects of the war caused a great depression. To find any date when the unfilled orders of the United States Steel Corporation were as low as on June 30 it is necessary to go back to November, 1911. This is of more significance than the rapid drop in the production of pig iron and ingots, because the unfilled orders give no promise for the months to come.

There are two very comforting things, however, in the situation. One is that we have slid down hill with great rapidity since March without having been jolted or jarred. The other is the remarkable comeback being staged by the agricultural industry. American farmers apparently are going to have a fairly large profit on most of their products this year. It is true that much of that will have to be applied on debts contracted during the long series of lean years. With all that, however, the purchasing power of the farmer is going to be much greater from this time on.

#### Must Sell More Abroad

Many coal men are convinced that we cannot have sustained prosperity by taking in each other's laundry. To maintain our prosperity we must sell more abroad. When we sell abroad we must take our pay in gold, promises to pay, commodities or services. We now have most of the gold. It would threaten the continuance of the gold standard for Europe to have to part with any further considerable amount of its basic treasure. We have extended credit to Europe in excess of \$20,000,000,000. The point is being reached where we no longer can continue to accept credit documents. We cannot continue to take gold without laying ourselves open to a major catastrophe. Many believe the time

has come when we must begin to take more of our pay in commodities.

Shipping, insurance and other services, in addition to the expenditure of Americans abroad, do not go far toward meeting the situation. A generally held opinion among coal men is that not only must the Dawes plan be made effective but we must do our part by a scientific revision of our tariff. The thought is that we have drawn largely on the substance of the world. The demands which we had to supply during the period of reconstruction in Europe have resulted in a degree of prosperity here, but from this time forward our own prosperity is going to depend upon the prosperity of our neighbors.

While it may be that there are many operators of coal mines who do not see in their own situation a reflection of the European situation, representatives of the coal industry whose duties require them to mingle largely with the men engaged in production are agreed that the industry has within it an unusual percentage of men who follow through to their source the influences which affect the demand for coal and which will affect future demand. For that reason many coal operators are following the proceedings in London as closely as they watch the steel trade and other more immediate barometers. There is a feeling of confidence that the Dawes proposal will be put in operation.

The only fear is that France may demand the impossible in the way of guarantees for its protection once Germany is economically restored. Incidentally there are many coal operators who think that much of the post-war depression in Europe could have been avoided and the travail of the Ruhr escaped had the United States been willing to ratify the treaty guaranteeing France against unrighteous aggression.

The fall convention of the American Chemical Society will be held at Ithaca, N. Y., Sept. 8-11, 1924. The Gas and Fuel Section is arranging as part of the program a round-table discussion on "The Storage of Coal and Spontaneous Combustion." Prof. S. W. Parr, of the University of Illinois, will lead in the discussion.

### Henry Ford Buys Dock At Last

A deal was closed July 16 by which Henry Ford acquires complete ownership of the dock of the defunct Superior Coal & Dock Co. at Superior, Wis. It was at first announced that the Ford interests had leased the property, but within a few days the outright purchase had been arranged. The Ford interests assume full responsibility for the outstanding bonds, including all back interest and overdue retirements, and will lift a mechanics' lien of \$175,000 held by the Brown Hoisting Machinery Co. and will pay off certain other accounts. The exact purchase price of the dock was not given out but it is known to be in the neighborhood of \$780,000. Mr. Ford is now in the lake coal trade. He has two large new vessels in the water and two more building. They are Diesel-engine driven.

### Union "Army" Closes Mine, Threatens Another

An armed band of about 100 miners on July 18 descended on the Kali-Inla mine, at Cambria, on the Pittsburg-Latimer county line, Oklahoma, overpowered the guards at the mine and forced a non-union crew to quit work. The guards were disarmed and forced to accompany the assailants as they motored into Latimer County after the attack.

The invading party assembled at Cambria several hours in advance and cut telephone wires into the little settlement before proceeding to the mine workings. It is understood that the attack was made by miners from Texas fields, Henryetta, Okla., and other mines nearby.

The Kali-Inla mine, after a long suspension, had recently resumed operations on the basis of the 1917 wage scale, which was opposed by officials of District 21, United Mine Workers.

A threat of similar action on the following day was conveyed to employees of the Deegnan & McConnell mine, Wilburton, Okla., which also is operating on an open-shop basis. The invasion failed to take place, however, and 100 men went to work. After several hours had passed without the appearance of the invaders, Sheriff Parks said he believed that any danger was over.

## Coke Output Low in June With Iron and Steel

In company with the production of iron and steel, the output of coke was reduced sharply in June. The total quantity produced was 2,958,000 net tons, of which 2,403,000 tons was from byproduct ovens, and 555,000 tons from beehive ovens. Comparison with May shows decreases of 14 per cent and 27 per cent respectively.

The present monthly rate of byproduct coke production is 23 per cent below the average for 1923 and is less than at any time since early in 1922. The average daily output in June was 80,087 tons, a decrease of nearly 11 per cent. The relation of production of capacity was 66.4 per cent. Of the 71 byproduct plants in existence, 66 were active and 5 were idle throughout the month. Ovens affiliated with iron furnaces produced 80.7 per cent of the total output.

Activity at the beehive ovens has decreased to the point where the monthly rate of output is but 38 per cent more than the weekly rate a year ago.

### Monthly Output of Byproduct and Beehive Coke in the United States\*

Monthly Average	(In Net Tons)		Total
	Byproduct Coke	Beehive Coke	
1917.....	1,870,000	2,764,000	4,634,000
1918.....	2,166,000	2,540,000	4,706,000
1919.....	2,095,000	1,638,000	3,733,000
1920.....	2,565,000	1,748,000	4,313,000
1921.....	1,646,000	462,000	2,108,000
1922.....	2,379,000	714,000	3,093,000
1923.....	3,127,000	1,497,000	4,624,000
April, 1924..	3,010,000	1,079,000	4,089,000
May, 1924..	2,786,000	761,000	3,547,000
June, 1924..	2,403,000	555,000	2,958,000

\* Excludes screenings and breeze.

The production of coke in June required the carbonization of 4,327,000 net tons of bituminous coal, of which 3,452,000 tons was used in byproduct ovens and 875,000 tons in beehive ovens. Thus the rate of coal consumption by the coke industry has decreased 31 per cent since the beginning of the year and is now 32 per cent less than the monthly average of 1920 and 37 per cent less than that of 1923.

### Estimated Monthly Consumption of Coal for Manufacture of Coke†

Monthly Average	(In Net Tons)		Total Coal Consumed
	Consumed in Byproduct Ovens	Consumed in Beehive Ovens	
1920.....	3,684,000	2,665,000	6,349,000
1921.....	2,401,000	706,000	3,107,000
1922.....	3,421,000	1,107,000	4,528,000
1923.....	4,458,000	2,358,000	6,816,000
April, 1924..	4,324,000	1,702,000	6,026,000
May, 1924..	4,002,000	1,200,000	5,202,000
June, 1924..	3,452,000	875,000	4,327,000

† Assuming a yield in merchantable coke of 69.6 per cent of the coal charged in byproduct ovens and 63.4 per cent in beehive ovens.

## U. S. Coal Exports and Imports Decline in First Quarter

Exports of coal and coke from the United States during the first three months of 1924 were 17 per cent less than for the corresponding period of 1923, according to the Chamber of Commerce of the United States. Imports of coal and coke during the same period fell off 83 per cent as compared with the first quarter of 1923.

## Lady Rhondda Still Seeks House of Lords Seat

Lady Rhondda, Great Britain's "Queen of Commerce," is said to be preparing for another battle with the House of Lords. She wishes to assume her seat in that august assembly as a peeress in her own right, the holder of a hereditary title. She is the most persistent of some dozen British peeresses in their own right who are excluded from the House of Lords on account of their sex.

The noble lords and barons of the realm have been greatly perturbed by these clamorous ladies since 1919, when women became eligible, on a basis of complete equality with men, to all English public offices. So far, the peers have successfully preserved their precincts from the threatened inroads of women.

## Monongalia Mines Seek Cut In Baltimore Scale

A meeting of the joint board of the Monongahela Coal Association of West Virginia and the United Mine Workers held a few days ago brought out the fact that the operators who subscribed to the Baltimore agreement are not at all satisfied with the obligations it has imposed upon them and are sustaining losses because of the high wages they have to pay. The meeting was held to adjust local differences growing out of the agreement. There was no official statement following the meeting but it became apparent that there was dissatisfaction among both operators and miners over the present working agreement.

The miners charge that the provisions of the new agreement are not being observed in all instances, alleging that local working conditions are not conducive to pleasant work and that extra pay for working in wet places is not being allowed.

The operators on their side contend that they are losing money on every ton of coal they mine and ship and that they will lose less money by suspending operations at their plants.

Representing the operators at the joint board meeting were Samuel Pursglove, R. M. Davis, Stephen Arkwright and W. R. Mitchell, the miners being represented by Van A. Bittner, J. K. Studdard, C. F. Davis and John X. Cochran.

Some operators have pointed out that more non-union coal is being mined in the Monongalia field than is coming from union mines and therefore they have asked the union to agree to a reduction in the scale so as to permit union mines to compete with the non-union mines.

"In the event of a failure to adjust the scale," one operator has declared, "we will be forced to close our mines or go to the non-union ranks."

## Trade-Data Ruling Unlikely Before Election

The difficulty of explaining a policy on a controverted question may preclude the Department of Justice from making any announcement on trade-association statistics before the election. Any pronouncement which might be made at this time on that subject, in the opinion of politicians, would be capitalized by the opposition during the campaign. Regardless of the attitude the department might assume, it would be difficult for it to justify its position in the short time intervening before the election, the politicians think. While no comment on the matter is forthcoming at the department, it is the opinion in other well-advised quarters that nothing will be done until after the election.

There is reason to believe that the new Attorney General is in thorough sympathy with removing any uncertainty that may surround trade-association activities. He is thought to realize, however, that it is difficult to know just how a line can be drawn which would clarify the matter. It is certain that there is no disposition to allow the study now being made of the general subject to interfere in any way with the prosecution of those who are using the trade association as a cloak to defeat the purpose of the anti-trust statutes. On the other hand, there is reason to believe that trade associations that are engaged in those activities which are generally recognized as being legitimate are in no danger of prosecution.

## Output of French Coal Mines Gains Steadily

Coal output from the French mines during April totaled 3,640,797 tons for 25 working days, which compares favorably with the March extraction of 3,772,734 tons for 26 working days, according to advices received by the Bankers Trust Co. of New York from its French Information Service.

The average daily output has constantly increased since the Armistice, comparative figures being:

	Average Daily Extraction
Year 1913 .....	136,147 tons
Year 1923 .....	121,064 tons
January, 1924 .....	144,680 tons
April, 1924 .....	145,632 tons

The average daily output from the mines situated within the pre-war frontiers of France is now only 7,155 tons less than in 1913, while the Lorraine mines are producing 16,640 tons a day more than in 1913.

Fuel imports into France during May were as follows: Coal, 2,594,882 tons; coke, 521,888 tons; patent fuel, 77,099 tons. The figures for April were 2,228,024 tons of coal, 703,446 tons of coke and 54,205 tons of patent fuel. May exports included 247,192 tons of coal, 34,434 tons of coke and 11,720 tons of patent fuel, compared with 178,781 tons of coal, 49,711 tons of coke and 8,157 tons of patent fuel in April.

## I. C. C. Issues Warning Of Car Shortage If Coal Movement Is Long Delayed

The Interstate Commerce Commission urges increased production and purchase of coal in a warning against a car shortage in the autumn, issued July 19. The fall months are usually the peak months of transportation, the commission said, and if the carriers are called upon to handle an enormous coal traffic during those months in addition to the other commodities which they are called upon to transport, their facilities will be taxed to the utmost, the commission declared.

The necessity for increasing coal production prior to the peak movement, in the opinion of the commission, would seem apparent if the public is to avoid transportation difficulties.

In sounding its warning, the commission emphasized the following conditions which may cause a car shortage:

"The average production of bituminous coal per year for the past seven years (exclusive of the strike year 1922) has been approximately 520,000,000 tons. The average production in the last six months of such years was 6.8 per cent greater than the average for the first six months. For the first half of this year production has been about 227,639,000 tons. If in the last half of this year production is 6.8 per cent greater than in the first half, the total for the last six months will be 243,118,000 tons, or an average of 9,500,000 tons weekly for weeks of six working days each. Since April 1, 1924, the bituminous coal produced has been less than 7,500,000 tons per week in each instance.

### Emphasizes Danger of Delay

"It can readily be seen, therefore, that if shipments of bituminous coal for winter consumption are deferred for any considerable length of time, the railroads will be called upon to handle a very large quantity of coal during the peak movement in the fall.

"The aggregate of bituminous coal shipped via lake to the Northwest during the 1924 season of Lake navigation to June 30, plus bituminous coal stocks at the head of the lakes April 1 of this year, is 12 per cent less than the corresponding figure for 1923 and 16 per cent less than the corresponding total for 1921, although larger than in 1920 and 1922. However, during the fall months of 1920 and 1922 there were severe car shortages and in the latter year a miners' strike.

"The coal stocks on docks at Duluth, Superior, Ashland and Washburn on June 15, 1924, aggregated 3,125,663 tons as compared with 2,179,999 tons on June 15, 1923, or an increase of 944,664 tons, indicating that considerably less coal has been distributed from the head of the lakes than at this period last year.

"Roads in the Northwest will soon be taxed to their utmost with the heavy demand on transportation in the fall months, during which period we will undoubtedly have a very heavy movement of agricultural products. It is therefore urgently suggested to the people of the Northwest that they pur-

E. J. McVann

Again secretary of the Smokeless Coal Operators' Association, having assumed the duties of the office July 1. Since relinquishing this post several years ago Mr. McVann has represented the smokeless operators in a legal capacity before the Interstate Commerce Commission and other tribunals.

chase their coal early, in order to avoid a curtailment in the transportation necessary for the heavy movement of agricultural products.

"There are no definite records available respecting present coal stocks. The stocks as of Jan. 1, 1924, aggregated 62,000,000 tons. At that time railroad coal stocks totaled 19,367,956 tons, as compared with 15,530,327 tons June 1, which is a decrease of 20 per cent. If the same percentage of decrease is applied to the aggregate coal stocks, the figure as of Jan. 1 would be reduced to 49,600,000 tons; which may not be a fair approximation of the coal stocks as of June 1, 1924.

"It is thought advisable to call the attention of the public at this time to the foregoing situation. The fall months usually are the peak months of transportation, and if the carriers are called upon to handle an enormous coal traffic during those months in addition to the other commodities which they are called upon to transport, their facilities will be taxed to the utmost.

"The necessity for increasing coal production prior to the peak movement would seem apparent if we are to avoid transportation shortages."

## Coal Consumption and Power Output by Utilities Wane

Electric public-utility plants consumed 2,834,266 net tons of coal during May, according to a report by the Geological Survey. This compares with 2,900,864 tons consumed in April, according to the corrected figures. Fuel oil consumed by utility plants in May totaled 1,166,315 barrels, compared with 1,215,111 barrels in April.

The average daily production of electricity by public-utility power plants during May was 154,700,000 kw.-hr., about 2 per cent less than the daily output in April.

## Davis Not To Be Judged By His Legal Service

The legal service of John W. Davis, candidate for President on the Democratic ticket, is no index of his views, according to the New York *Evening Post*. "When one comes to placing a portrait of John W. Davis alongside those of Mr. Coolidge and Senator La Follette to suggest what kind of a man the Democrats have put up for President," says Clinton W. Gilbert in his column, the Daily Mirror of Washington, "one has to wrestle with difficult questions whether he is a conservative or a progressive.

"While the convention was going on I lunched in a Wall Street luncheon club. Everybody there wanted to see him nominated for President. They thought they recognized him as one of their own kind. On the other hand, all the campaign literature describes him as a progressive. Is he a liberal because he once appeared for 'Mother' Jones and Eugene V. Debs in an injunction case and because he recently acted as attorney for a labor union, the National Window Glass Workers? Or is he a conservative because he is counsel for J. P. Morgan & Co. and for a telephone company?

"Here is the story of the defense of 'Mother' Jones and Debs as told by Colonel J. C. Johnson of Clarksburg:

"Do you see that hill?" he asked. "Well, on top of it, more than twenty-five years ago, John W. Davis saved 'Mother' Jones and Eugene V. Debs from a lynching." Now, the old man was referring to the events that led up to Mr. Davis' first case as a lawyer. It was at a mine strike in 1898 and 1899. 'Mother' Jones, grizzled warrior for the labor cause, and Mr. Debs had come here to lead the union miners. The mine owners obtained an injunction against the strikers, and when Mr. Debs and the venerable woman refused to abide by it they were surrounded out on 'T. K.' hill by angry townspeople and non-union miners. They were in the midst of a dangerous swarm. The angry mass moved forward apparently to wreak summary treatment. It was at this juncture that Mr. Davis, recently out of Washington and Lee University and flushed with his first undertaking, mounted a shabby wagon and delivered an impassioned plea. He denounced the injunction as high-handed and against all the institutions of this country and pleaded that reason take the place of mob spirit. He was successful in getting the endangered strike leaders to safety, and subsequently went into court and defended them. He won. It was his first legal victory.

"It is only fair to brush aside all of Mr. Davis' legal employment in trying to make up our minds what his views are. He isn't a progressive because he has appeared for 'Mother' Jones nor a conservative because he has appeared for Mr. Morgan. He is only a lawyer taking cases as they come to him. He defines his own attitude thus: 'I conceive it to be the duty of a lawyer, just as it is the duty of a priest or surgeon, to serve those who call on him, unless, indeed, there is some insuperable obstacle in the way.'"

## Ohio Miners and Operators Agree to Modify Scale

An agreement was signed at Logan, Ohio, July 18 by the joint conference of operators and miners in the southern Ohio field which virtually puts into effect the agreement in the No. 8 field of eastern Ohio. The joint conference held sessions for about ten days and every important point in the scale and working conditions was gone over thoroughly. The operators asked for a number of concessions, which were granted, and as a result it is hoped that production in the southern Ohio field will be stimulated when market conditions improve. Dead work and the removal of slate will not be so expensive and the cost of producing coal will be lowered as a result. Another provision imposes heavier penalties for the loading of dirty coal and it is proposed to enforce them.

## Corbin Amalgam Plant Nearly Ready

The Corbin Coals, Ltd., formerly the Corbin Coal & Coke Co., is installing at Spokane, Wash., an amalgam plant costing about \$100,000, to prepare the smaller sizes of coal. This is a new method of treatment the product of which is said to be a fuel that is exceedingly popular with the consumer, among its virtues being almost total freedom from smoke and ash. The plant is reported to be almost ready for operation. A coal washery is being placed at Corbin to clean coal larger than  $\frac{1}{2}$  in. in size and will be ready soon.

The Corbin coal lies in huge vertical seams or lenses and some 10 or 12 of these have been found on the company's property. The Mammoth Mine, which is developed to the point of producing about 250 tons a day, is opened up on a lens 450 ft. thick. The depth so far proved is 300 ft., with every evidence that it continues several hundred feet deeper. The seam has been traced over the mountainside for about a mile. Owing to the peculiarity of the formations the coal varies in grade and quality. In places it is of the nature of anthracite and in other places soft and easily broken. A number of small bands of shale make it difficult to clean and have led to the introduction by the company of the modern plant.

## Museum of Engineering And Industry Asks for Nine Million Dollars

One million dollars has been assured toward the establishment of the National Museum of Engineering and Industry, Inc., with headquarters in the Engineering Societies Building, New York City. A campaign to raise an additional \$9,000,000 started July 5. The president of the new organization is Dr. Elihu Thomson, who received the Kelvin Gold Medal from the Royal Society at the Kelvin centenary in London on that same day. The vice-presidents are Dr. Edward G. Acheson, one of the creators of the modern abrasive industry; Dr. Leo H. Baekeland, inventor of Velox paper and Bakelite, who is president of the American Chemical Society, and Dr. Edward Weston, creator of the Weston type of electrical instruments.

In co-operation with the Smithsonian Institution the new organization is planning to erect on its grounds in Washington a building to house the original models of early inventions and the records of constructive achievement of pioneers, inventors and engineers in the development of transportation and industry. In this way the United States will be given the kind of institution which all the great European nations have possessed for years, and in the layout of the proposed museum use will be made of the data collected by an expert who has recently returned from a year's survey of museum practice abroad.

### To Make Special Collections

An important departure in the American scheme is proposed, however; made necessary by the vastness of the country. In addition to the central collection at Washington special collections such as replicas of the historical exhibits will be carried to the people, also live machinery of modern processes will be placed in affiliated museums in industrial centers of every state.

Already old models and records long forgotten have been located and resurrected and this winter will be exhibited at the headquarters as a demonstration of how the ultimate collection will appear.

## Illinois Rate Boost Deferred; May Reopen Whole Case

New Northwest rates raising Illinois coal 28c. to the Twin Cities will take effect Sept. 10 instead of Aug. 21, according to the latest decision of the Interstate Commerce Commission, announced to Western carriers July 21. This puts one more kink into the tangled skein of Northwest coal rates. The new schedules were postponed to give railroads time to publish them. Incidentally it gives time for one more petition to the commission to reopen the whole Northwest rate case.

Illinois coal operators are the latest to file, following in the wake of six other protesting groups. Illinois claims there is no justification for advancing that state, that the commission erred in its findings of undue discrimination, that the commission erred in not taking the whole origin territory into consideration, that the 'order compels violation of the fourth section of the Transportation Act by failing to find illegality in existing rates to the Twin Cities, at the same time ordering increases to intermediate points. Illinois also claims the I. C. C. examiner excluded proper testimony that justifies reopening the case.

## Cutting-Machine Runners Strike at Orient Mine

The new machine-loading scale signed July 15 by the miners' union and the Chicago, Wilmington & Franklin Coal Co., Chicago, produced a strike at the mine. On the morning of the 16th, when the scale took effect, all the cutting-machine runners at the Orient No. 2 mine declined to go below. They could not make a satisfactory agreement with the mine superintendent for their tonnage payments. The new agreement signed by union officials provided that until the company gets weighing equipment installed, the cutting machine men's pay would be fixed by agreement. The company refused to discuss the case until the men went back to work under the general working agreement. This they had not done up to Saturday, so the mine stood idle.

## Reeves Dock at Superior To Be Rebuilt at Once

Announcement has been made of the plans of the reconstruction of the Reeves dock at Duluth-Superior, Wis., which was reported under demolition several weeks ago. The Reeves Coal & Dock Co. has been formed under the laws of the State of Delaware, and will construct a 500,000-ton dock on the present site as soon as plans are finished. The dock will cost \$750,000. Plans are being drawn by the Fegles Engineering Co. Contracts will be let as soon as these plans are completed. The dock property is located on the highway between Duluth and Superior and is considered the best dock property in the harbor.

The Reeves company has announced a "coal-at-cost" policy, which will mean that 500 dealers throughout the Northwest will save 25c. a ton.

Forestation by Clearfield Bituminous Coal Corporation, of Clearfield, Pa.

Thirty-eight coal companies set out more forest trees than any other group of tree planters in Pennsylvania during 1923. The Clearfield corporation was the leader, planting 163,000 trees. Of the corporation's 150,000 acres of coal holdings, 24,000 are owned in fee and available for reforestation.

## Practical Pointers For Electrical And Mechanical Men

### Various Forms of Gears and Their Uses

Spur Gears with Shafts Parallel—Bevel Gears with Shafts at Angles but in One Plane—Worm Gears with Shafts at Right Angles but in Different Planes

BY GUSTAV H. RADEBAUGH  
Urbana, Ill.

**T**HE gears used on mine machinery are made from wrought steel, cast iron, bronze, brass, malleable iron, rawhide, fiber and steel castings. In general practice, malleable iron gears are made by casting the metal in molds of appropriate shape. Sometimes steel gears are made in the same way. Cast iron is used both for cast and machine-cut gears. The gears made from mild, tool and alloyed steels, bronze, and brass generally carry machine-cut teeth.

Gear cutting is an extremely delicate job, requiring special machines which are designed to space the teeth properly and give them the required contour. This is why machine-cut gears cost so much more than cast gears and are of superior quality. The teeth on the cast gear are not formed by a machine, but are merely cast in the sand and consequently do not have as perfect a shape as those which are machine-cut.

#### CUT GEARS FOR TRANSMISSION

Cast gears are used extensively on certain kinds of mine machinery, and they serve their purpose admirably. For power transmission the cut gear is generally used. Several styles of gears are used for transmitting power. When using gears, power is transmitted without slippage or lost motion so long as the teeth retain their shape.

The most familiar gear is that having spur, or radial, teeth. The small gear, shown in Fig. 8 meshing with the spur gear, Fig. 9, is called the pinion. This type of gear can be machine-cut or cast. The sizes of the gears are determined by the size of the teeth. The most common sizes are the 16, 12, 10, 8, 6 and 4 pitch. By a No. 4 pitch gear is meant one having four teeth for every inch of its diameter—hence, the pitch is equal to the number of teeth per inch of diameter. For example, if a gear has 60 teeth and the diameter of the pitch circle is 10 in. its diametral pitch is 60/10 or 6, and the gear is therefore called one of No. 6 pitch.

It is not difficult actually to determine the pitch of a gear, but if in doubt as to the procedure, and it is necessary to secure this information for a replacement order, a simple plan is to mark out the shape of six or eight teeth on a piece of paper and with this

drawing give the number of teeth and the outside diameter. It is then a simple matter for the supply house to figure the correct pitch of the gear. In order to obtain a gear of the proper dimensions to fit the requirements, the bore of the hole, the size of the key seat and the width, length and diameter of the hub should be given also. The spur gear, as can be seen from Figs. 8 and 9, is used for transmitting power from one shaft to another parallel to it.

Bevel gears, Fig. 13, which may be either cut or cast, are designed to transmit power to shafts which are not parallel but lie at some angle to each other in the same plane. They may be arranged to work at any one of many given angles. Bevel gears and bevel pinions are shown in cross section in Figs. 14, 15 and 20. The pair in Fig. 14 has the two shafts at an angle less than 90 deg. The one below has an angle greater than a right angle. In the lower left hand corner of the illustration the angle is still greater, and the larger wheel is known as an inside bevel gear. These three drawings illustrate the wide range of usefulness of this device for transmitting power through various angles.

#### RAWHIDE GEAR ALMOST SILENT

The miter gear, Fig. 18, is a bevel gear in which the shafts are at right angles, the gears have the same number of teeth and the pitch or contact cones are of the same size. Rawhide gears, Fig. 16, are used to advantage on high-speed work. One member of a pair or train of the spur and bevel gears are often made from rawhide, fiber or some similar material. One reason for using gears of this kind is that they run almost noiselessly. The rawhide is supported on each side with steel or brass plates held in position by rivets passing through the gear body.

Racks, Fig. 19, are used frequently on mine machinery. The size of the rack is determined as in the spur gear. One of the most common difficulties with the rack, especially those made from cast iron, is the fact that they are liable to break in two. Ordinarily this is caused by not having the rack firmly and evenly fastened in position. Severe stresses are also placed on the rack when quantities of dirt and grit

are allowed to collect between the teeth.

The worm and worm wheel, as shown in Fig. 11, are a combination of a screw and a gear and are used for transmitting motions from one shaft to another at right angles to it, the shafts not being in the same plane. This type of gearing is used when it is desired to change small torque at high speed to high torque at low speed. The most common use of the worm and worm wheel is in steering gear construction and small electric motor drives. The worm, as a reference to Fig. 11 will show, is simply a screw whose threads fit the teeth of the worm wheel. The worm wheel may be a plain spur gear with the teeth cut at an angle or curved to fit the worm. These wheels are of two types, the hobbed-work wheel Fig. 10 or the gashed-tooth worm wheel, Fig. 12. The shapes of these wheels are clearly defined in the plate.

#### MUST KEEP CHAIN GRIT FREE

The link belt or silent chain as shown in Figs. 1-7, is used on drives in the power plant of the truck, gasoline locomotive and automobile. To get the best service from this type of drive it is essential that the chain be kept properly lubricated and free from grit and dirt. When a chain becomes stiff and dirty from the accumulation of foreign material, free it from the drive by removing a pin and bushing. Then clean it well in a bath of gasoline. Cleaning the chain in a hot bath of water and salsoda is also considered good practice. After the chain is thoroughly cleaned, using either method, it then should be immersed in a good quality of hot lubricating oil and permitted to soak in this hot bath for a half hour.

The sprocket wheel is usually made from cast iron, although some of the small sizes are made from malleable iron. If these sprocket wheels break and it is impossible to get a replacement from the factory when needed, the broken wheel can be used as a pattern from which a new wheel may be cast at a near-by foundry. When fitting a new sprocket wheel on a job always test the wheel with the chain. This is done by testing the fit of the chain around the entire circumference of the sprocket wheel. Remember the chain is the standard and that the wheel must be fitted to it. Some of the chains used on sprocket wheels wear out quickly and when this happens the shape of the chain is possibly at fault and not the material. Inspect the sprocket wheel, and a large or uneven tooth may be discovered which is causing the damage.

Some of the Gears and Link Equipment Used for Transmission of Power

Figs. 1 and 2—Silent link chains; Fig. 3—Sprocket wheel; Fig. 4—Ewart link belt; Figs. 5, 6 and 7—Attachments used with Ewart link belts for conveying purposes; Figs. 8 and 9—Two views of spur gearing; Fig. 10—Helical gear; Figs. 11 and 12—Worm and worm wheels. The thread of the worm is left-handed. On the left hand is a hobbed-work wheel and on the right

hand a wheel with gashed tooth; Fig. 13—Bevel gear; Fig. 14—Bevel gear with angle of axes less than 90 deg.; Fig. 15—Bevel gear with angle of axes more than 90 deg.; Fig. 16—Rawhide pinion; Fig. 17—Spiral gear; Fig. 18—Miter gear; both gears same size and angle between them a right angle; Fig. 19—Steel rack; Fig. 20—Inside bevel gear and pinion.

A large number of special attachment links for sprocket chains are made. These are most commonly used to hold conveyor flights and the like. Three of these links are shown in the plate. In this type of chain the links are made from malleable iron. Chains,

after they have been in service for a long time become loose in the joints, causing the chain to unhook. This may be overcome by closing the hooks at the ends of the links so that they will fit the bar of the adjacent link more closely.

### Repair of a Steam Engine Crankpin

The crankpin on a 200-kw. engine-driven generating unit had been heating and giving much trouble for quite some time. Often it had been necessary for the engineer to spend nearly all of his time oiling the bearing and in many other ways taking care of the crankpin. A thorough investigation revealed nothing wrong with the pin; it was in the proper alignment and of proper diameter.

The mechanical engineer of the plant finally ordered a new pin, but the attendant was not entirely satisfied that

a new one was needed and therefore made a close examination and found a small crack from which the oil would run out when he clamped the sides of the pin together. The crack was so thin that it was almost impossible to see it with the naked eye. It was large enough, however, to explain the difficulty. The pin while running would expand and cause the fracture to open up and bind in the bearing box, cutting the box out. As shown in the illustration a thin bushing in the shape of a sleeve was shrunk on the crankpin and a hole drilled through the crankpin and bushing to accommodate a pin for holding the sleeve in position. After

the ends of this pin had been filed down the crankpin was again put in place and no further difficulty experienced.

### Quick Repair to Crankpin

A sleeve was pressed over the whole surface of the crankpin and a pin driven through to hold it in position. In this way the crankpin was given a new smooth surface and heating of the bearings permanently stopped.

## Problems In Underground Management

### Rock-Dusting Machine with Three Fixed Outlets Treats Roof and Ribs

Is Mounted on a Single Truck and Does Not Need Services of a Nozzleman  
— Dust Does Not Pass Through Fan

NOW that the coal-mining industry is convinced of the utility of rock-dusting as a safety measure the chief problem confronting the coal producers is that of finding the best method or machine wherewith to apply the dust. Various portable blowers are now in process of construction. Among them is the Miller mine-dusting machine designed by James B. Miller of St. Louis, Mo., and shown in the accompanying illustrations. The first of these machines has just been put to work experimentally in the mine of the Valier Coal Co., Valier, Ill., near the properties of the Old Ben Coal Corporation

bottom of which extends a screw conveyor transporting dust to one end and delivering it at a point directly beneath a multiple outlet through which a fan is driving a blast of air. The dust is picked up by this current and is discharged through three rectangular outlets, two of which are directed toward the ribs at a slight elevation above the horizontal while the third is aimed directly at the roof. None of the dust passes through the fan itself. The dust is drawn from the conveyor pipe beneath the fan and swept upward through the outlets, the inlet apertures being below the fan casing.

The fan is 12 in. long and revolves in a drum housing of light sheet steel. The three discharge pipes, all the air and dust inlets of which are at the bottom of the drum, curve upward and around the circumference of the casing delivering the dust streams at three angles so as to effect complete coverage of ribs and roof. The traveling speed of the truck can be varied somewhat without changing the volume of dust delivered per lineal foot of entry. This is done by altering the speed of the motor which drives the screw conveyor. This change of speed modifies the quantity of dust drawn from the bin, the speed of the totally-inclosed dust-proof motor driving the fan being similarly changed.

After much experimentation Mr. Miller determined upon what he thinks is a proper ratio of dust delivery as between outlets. This is partly governed by the sizes of the discharge pipes. The cross section of the two outlets delivering dust to the ribs is in each case 5x8 in., the perpendicular pipe directed at the roof being only 2 in. wide. Were there no other controlling factor, the sizes of the pipes thus would divide the dust discharge so that five parts would strike each wall and two parts would be distributed on the roof.

But there is a further control of this proportion. It is effected by the adjustment of sleeves fitted around the feed pipe by means of which the screw delivers dust to the fan. The feed pipe bears a wide slot along its top for the full 12 in. under the fan chamber. This aperture can be widened or narrowed under each discharge pipe by revolving the sleeve of that section of the

FIG. 1  
Side View of  
Rock-Dusting  
Machine

This shows both motors, one totally inclosed driving the fan with its three outlets and the other driving the dust conveyor through back gearing and chain. Note that both dust bin and fan casing are of welded construction.

where much of the work of adapting rock-dusting to the mines of this country was done by J. E. Jones, safety engineer for Old Ben.

The Miller duster was designed after Mr. Miller had spent several weeks in the Old Ben mines studying the dusting problem in company with various engineers. It differs in two main particulars from most of the other dusting machines now in the development stages. In the first place this machine in its entirety is mounted on one truck instead of having the dust bin on one truck and the nozzle on another. The other main difference between it and other machines designed for a similar purpose is the fact that the dust is discharged through three fixed outlets instead of through one flexible pipe. This reduces the crew necessary for the operation of the machine by one man as no nozzle has to be manipulated.

The Miller duster may be briefly described as follows: The machine consists of a bin of three tons capacity along the

FIG. 2  
End View Showing  
Electrical  
Control

It is, of course, intended to mount the entire mechanism shown in this illustration on a truck that may be pushed or pulled through the mine headings by a locomotive. One operator controls the entire machine and has practically nothing to do while it is in operation.

feed pipe. By a nicety of sleeve adjustment, the same volume of dust can be discharged from each outlet, or the proportions blown against the top and the two ribs can be changed to suit the needs of the place to be dusted.

One or two engineers, upon seeing the drawings and photographs of this machine for the first time, have wondered whether the three dust-laden air

streams from the machine might not set up conflicting air currents and eddies in certain parts of the cross section of an entry that would prevent dust from reaching the angles between roof and ribs. This possibility was, however, considered in building the machine and the difficulty obviated by properly adjusting the force of the air blast.

## Why Exhaust Only Tenth of One per Cent Of Your Mine Development Daily?

**Takes Five Years to Extract One Hundred Acres—Should Follow Automobile Industry in Planning Rapid Sequence of Operations—Ventilation Problems Vexatious in V-System of Mining**

AT THE bi-monthly meeting of the mining section of the Engineers' Society of Western Pennsylvania, evening of June 24, 1924, in Pittsburgh, E. B. Moore, who is Pittsburgh manager of the Coal Service Corporation, talked on "Concentration in Coal Mining." F. A. McDonald, general superintendent of the National Mining Co., presided.

In room-and-pillar mining, according to Mr. Moore, the average output per place worked is less than 10 tons. A mine with a capacity of 1,000 tons of coal per day, therefore, requires about 150 working places, allowing for idleness of 50 per cent of the places, which is generally a safe assumption. These places are quite likely to be scattered over an area of 100 acres, from which, in a thick seam, only about one-tenth of an acre is actually extracted per day to yield 1,000 tons. The ratio of the area extracted per day to the area developed is as 1 is to 1,000. It would take about five years to work out the developed area at this rate of mining by the use of the present methods.

### NEW MEANS AND NEW WAYS

Two ways to mine coal intensively are at the disposal of every operator, (1) by the use of new and modern equipment, (2) by resorting to some modification of longwall or room-and-pillar mining. The ideal system involves a combination of the two. In the mines where the room-and-pillar method is the only choice, mechanical equipment will serve to lower production costs. The day may come when three or four cuts will be taken per day from each working place. A prominent mining engineer proposes to do that very thing, by stationing three hand loaders in each of two adjoining rooms which are to be cut alternately and the coal loaded onto conveyors. "Many operators say such intensive mining can't be done profitably," remarked Mr. Moore. He is confident that it can by giving due regard to mine layout and by close supervision.

In his optimism he contrasted present mining methods with the modern production methods employed in automobile factories, where a thousand and one operations are performed successively with little loss of time. He sees no reason why mining cannot be speeded up by the elimination of lost

time between the half dozen operations performed at the face.

In a few years, he is disposed to believe, the fuel requirements of this country will be met mostly by mine owners who take advantage of labor-saving equipment to reduce the cost of production. A company now using modern equipment and a concentrated system of mining reports a saving of 30 to 35 per cent over the cost of producing coal by the room-and-pillar method.

Roof control is the chief factor standing in the way of mining extensively by concentrated systems in which longwall mining is involved. Heretofore not enough attention has been given to the potentialities of long faces, which, where they can be worked successfully, lower the costs of driving headings, laying track, drainage, ventilation, etc.

### HAS INDUSTRY BEEN ASLEEP?

Mr. McDonald denied Mr. Moore's statement that the reason why the mining of coal is far behind the times is because of the failure of those engaged in this pursuit to adopt labor-saving machinery, and questioned whether more intensive mining and closer supervision alone would effect savings in the cost of production. He said the labor situation in the Pittsburgh district made such advances difficult, though some progress is shown in nearby non-union districts. Different conditions in every field, mine and section of a mine prohibit the adoption of any one general method for all mining.

An objection was raised by R. H. Scheller to the concentration of working places. He maintained that the chemical content of coal varies from place to place in a mine. Coal extracted from a large area, when mixed in dumping, is fairly uniform in composition from day to day, or month to month. Uniformity of ash, sulphur, phosphorus, etc., is highly desirable in coking coal for metallurgical use. His objection had no reference to steam coals.

R. W. Powelton wanted to know if mechanical loaders are being used anywhere in a concentrated system of mining, if longwall mining is being practiced at any mine in the vicinity of Pittsburgh and what percentage of recovery may be expected from concentrated mining. Mr. Moore replied

that a mine in Indiana is using Joy loaders together with the Movor conveyor in a concentrated system. The H. C. Frick Coke Co. is working the Pittsburgh seam on a longwall face at its Leckrone mine. Recovery from concentrated mine layouts should be higher than that obtained from rooms and pillars. The chief engineer of the West Virginia Coal & Coke Co. claims a recovery better than 95 per cent from the V-system of mining.

Graham Bright characterized E. C. Moore as being modest in not saying much about the V-system of mining which his firm advocates. During a visit in the Norton mine where this system is being worked, Mr. Bright noticed that the men were actively engaged in useful work practically at all times. Concentration permits factory-like illumination at the working face, eliminates many of the dangers prevalent in scattered workings and invites close supervision. He thinks that wherever the coal is clean loading machines of some type now in use can be used in conjunction with the Movor conveyor in the V-system of mining.

### VENTILATING THE V-SYSTEM

"How would the V-system work in a gaseous mine?" asked T. G. Fear, general manager of the Inland Collieries Co. He is not convinced that the system is safe when used in gaseous mines. A roof break might encroach on the points obstructing the path of the current of air with which the faces must be swept. Mr. Moore advocates the use of blowers or a brattice-cloth wall up the center of a gallery for ventilation purposes. Mr. Fear said that the practice of thus using brattice cloth is unsafe. The driving of two gallery entries to each pair of faces would provide better ventilation but would at the same time occasion other difficulties. Flame-proof motors undoubtedly will be furnished with the Movor conveyor wherever the conveyor is to be installed in gaseous mines, said Mr. Moore.

### Freakish Coals in Scotland

In a paper on "The Heat Due to Strata Movements and Its Effect on Certain Coal Seams," read before the North of England Institute of Mining and Mechanical Engineers, Newcastle-upon-Tyne, England, by Henry Briggs, A. L. S. Owen and John Wilson, reference is made to the earliest account of what has been known as "calcareous coal" because of the presence of large quantities of calcium, magnesium and ferrous carbonates, the first forming about one-third of the altered coal and the two others together another 12 to 20 per cent of its weight. This coal is found south of Motherwell, Lanarkshire, Scotland, between that town and the Clyde.

The alteration varies in extent from point to point in the 100 acres affected. It affects several seams but in an erratic manner, but it does not appear to extend deeper than 300 ft. Apparently the occurrence has relation to heat and to certain faults, of which the three principal ones converge at low angles and finally join.

# Production And the Market

## First Signs of Awakening Interest Come to Light In Bituminous-Coal Trade

A faint but none the less unmistakable awakening of activity in the Southwest is the first favorable tangible development in the soft-coal trade since the present depression set in. The increase, which is not large, is not so important in itself but is of far reaching interest as a possible portent. For some time the feeling has been strong that the beginning of a revival was at hand, but politics and various other reasons have been advanced as responsible for the delay in its appearance. Meanwhile the country's stockpiles continue to shrink to the danger point, though at a less rapid rate than many imagine, because of the slowdown in all lines of industry. Shipments by lake to the Northwest, too, are far below the seasonal average at this time. Reports of the reopening of textile plants continue to filter in, but these are offset by reduced working time at a number of others. Concurrently the trade continues to mark time as the process of readjustment develops, prices and production showing slight material change.

### Commerce Commission Warns Against Delay

Calling attention to the danger of transportation difficulties in the event of heavy traffic on the railroads in the autumn, the Interstate Commerce Commission issued a warning last week that coal purchases should be no longer delayed. Another interesting development was an agreement by miners and operators in the southern Ohio field modifying working conditions in such a manner as to enable mines in that district to compete more successfully with the non-union fields.

Coal Age Index of spot prices of bituminous coal advanced slightly during the last week, standing on July 21 at 163, the corresponding price for which is \$1.98.

There was a marked quickening in activity at Hampton Roads after the holiday, dumpings of coal for all accounts during the week ended July 17 totaling 373,600 net tons, a gain of 137,080 tons over the pre-

ceding week, when 236,520 net tons was dumped. Coal dumped at Lake Erie ports during the week ended July 20, according to the Ore & Coal Exchange, was as follows: Cargo, 733,634 net tons; fuel, 41,667 tons. The totals for the previous week were 731,438 net tons of cargo coal and 48,062 tons of fuel coal.

Production of bituminous coal recovered sharply from the slump caused by the holiday, output during the week ended July 12, according to the Geological Survey, totaling 7,455,000 net tons, which is the highest level attained since the week ended March 29. Anthracite output likewise registered a rebound to 1,871,000

net tons during the week ended July 12, compared with 1,296,000 for the preceding week.

Demand is far from brisk in the anthracite market, though the larger companies do not find it difficult to move domestic sizes other than pea, which is piling up on both companies and independents. Independent prices are weak, stove when taken alone bringing about 25c. more than when sold with another size. Egg also in some instances commands a little higher price than chestnut, being not quite so superabundant. Steam sizes are sluggish in the extreme, only the better grades of independent product being able to command anything like company schedules.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
June 28.....	10,458,000	7,371,000
July 5 (a).....	8,742,000	5,738,000
July 12 (b).....	10,925,000	7,455,000
Daily average.....	1,821,000	1,243,000
Cal. yr. to date (c).....	290,478,000	239,409,000
Daily average to date.....	1,772,000	1,461,000

#### ANTHRACITE

June 28.....	2,105,000	1,918,000
July 5.....	1,580,000	1,296,000
July 12.....	2,051,000	1,871,000
Cal. yr. to date.....	54,800,000	48,792,000

#### COKE

July 5 (a).....	376,000	94,000
July 12 (b).....	366,000	105,000
Cal. yr. to date (c).....	10,744,000	6,282,000

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Gains a Little Confidence

A slight indication of the pick-up to come in domestic coal has been felt in the Middle Western states during the past week. Country orders from dealers for certain prepared sizes have begun to trickle in slowly. This does not awaken the dealer trade in the cities, however, so there is little enough as yet to bolster up the flat condition of the market. Illinois operators are letting it be known that they intend hoisting the price of lump and egg 15 or 25c. Aug. 1. The general lifelessness of things has shut down three or four mines that have been trying to operate, and a couple of operators who had announced their intention of opening up July 15 changed their minds. Steam coal is draggy although many stocks are getting down toward the vanishing point.

Field conditions in Illinois continue discouraging. The railroads are about the only consumers that are taking anything from commercial mines and these shipments are not enough to provide much running time. More than half of southern Illinois continues shut down cold. The Jackson County and DuQuoin field is in even worse condition. Mt. Olive production is almost at a standstill, except at railroad mines, and the Standard district is absolutely flat.

Business conditions at St. Louis are quiet. There are few domestic orders although this trade is beginning to pick up in spots. Local wagonload steam has practically ceased and carload steam is so easy that it can hardly be found. Country steam also is hard to find, but here and there in the country there are indications that buying ought to be pretty good by Aug. 1, as there is some activity now to indicate that.

### Kentucky Feels Better

At least a few of the Louisville coal men have obtained some business over the week, and are feeling better. There have been some good state contracts placed, 646 cars of screening selling at from \$1.10 to \$1.25 a ton, and while these prices are low—around 75c. a ton under prices of last year—it has lent some encouragement.

It is also said that domestic consumers are stocking more freely and that retailers are buying more coal, including some yard stock. General industrial business is in small lots, and the utility, steel and other big consuming interests are not buying in sufficiently large quantities to make things interesting, according to coal men. Nevertheless, the market is being well maintained on screenings, in spite of fairly large production of prepared coal in eastern Kentucky.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	July 21	July 14	July 7	July 23
Index .....	163	162	164	197
Weighted average price .....	\$1.98	\$1.96	\$1.99	\$2.38

This diagram shows the relative, not the actual, prices on four-teen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Western Kentucky operators deprecate reports that the field is busy. It is true that tonnage has been picking up a little, but a large number of mines are closed down by strike, many small mines have not been operating, and the total capacity of operating mines is not much over 50 per cent of field capacity. But production is increasing and some of the operators and jobbers are looking forward to a much better market in August.

Although a little more interest is being manifested by foreign buyers in smokeless coal and although the price is a little higher at tidewater, nevertheless there is not as strong a demand for low-volatile fuel in Eastern or tide-water markets as there is in the West. There is hardly a sufficient supply of prepared grades to fully meet Western demand, as it does not pay producers to prepare too much tonnage because of the low prices prevailing on nut and slack.

Northwest Is Waking

Bituminous prices are the same at Duluth as last reported, but the market is considerably stronger in tone. An independent mining company has purchased 2,000 tons of Youghiogheny screenings on the market, and several other companies are in the field with a buying light in their eyes. A month ago none of the independent mining companies was even remotely interested in the coal business and the mines were shut tighter than a safe. Several large industrial concerns have begun to show signs of life.

While no indication of Mr. Ford's plans has been given since he acquired the Superior Coal & Dock Co.'s dock, it is rumored that he will bring coal here from his mines in

his own ships, of which he has two in water and two building, and will go into the coal business.

Inquiry comes from Winnipeg for hard coal and much is being shipped there, much to the joy of Duluth docks, as only the wealthy are filling their bins there. Prices are firm, with another 10c. advance sure on Aug. 1. The docks hold now about 3,300,000 tons, of which 2,400,000 is free. Thirty-five cargoes arrived last week, of which six were hard coal, and ten are reported on the way, of which one is hard. Shipments are keeping up.

The Milwaukee coal market continues quiet. Jobbers are scouring the country for business, but with little success. A change is not looked for much before September. Nobody seems to want coal just at present. Prices hold steady. The City of Milwaukee has let contracts for about 60,000 tons of coal for delivery to various municipal institutions during the coming winter. The prices, which vary according to length of haul, averaged \$1 per ton less than prices paid last year.

Receipts of coal by lake continue fairly liberal thus far, 339,038 tons of anthracite and 779,343 tons of soft coal having been received.

West Is Buying at Last

Mail orders from dealers for Arkansas semi-anthracite lump indicate that domestic storage is under way throughout the Southwestern district. Immediately before the advance of 50c. in the retail price early this month the heaviest business since last winter was reported. Wholesale prices still are quoted at \$5.50@\$6 for lump, \$3.50@\$4 for mine run and \$2 for screenings. Kansas strip-mine coal is quoted at \$3.75 for lump and \$3.50 for nut. There has been no change in Kansas shaft coal or the Henryetta (Okla.) product.

Conditions in the Colorado market are not much stimulated yet but a few storage orders have been received and operators expect conditions to be almost normal before long. Prices remain unchanged. The transportation and car supply has been very good throughout the state.

In Utah the recent increase in coal prices by operators and retailers has had the effect of stimulating storage business. Mines are working in excess of two days a week now and the output should grow steadily. Lump, which was a drug on the market a few weeks ago, is moving again. In fact, there is a little demand for every grade of coal now. Business is generally conceded to be better now than it was a year ago. Smaller manufacturing plants are buying coal again, as are big industrials such as sugar companies.

Ohio Markets Sluggish

Total lack of interest in the domestic situation marks the Cincinnati market. Retailers have quit buying and the shortening of the supply of residue has stiffened the slack market just a little in bituminous. Many Kanawha mines have suspended operation and some shutdowns are reported from southern Kentucky. Lake buyers still stand off; the tonnage taken is far behind that of last year. Smokeless business is sluggish with screenings the weakest point on the list. Retail deliveries are at the lowest ebb of the year and prices unchanged.

The trade at Columbus is in a slump. Up to recently there was a fair volume of domestic business, but it has dropped off, and orders are far apart and hard to get. This condition is expected to be temporary only, as the general reduction in stocks will soon force some of the larger users into the market. Retail prices are fairly steady at recent levels, but this is due largely to small retail stocks. Pocahontas, smokeless grades and splints are the most popular. Steam business is rather quiet as there is little contracting. While demurrage coal is not as plentiful as formerly, still a considerable amount can be picked up in the local market. School coal is moving in considerable quantities.

While the Cleveland market continues dull and steam demand is quiet, there have been reports of additional mines opening up in the field, and if this is not indicative of actual betterment in trade conditions it at least augurs well for impending improvement. Spot prices have softened slightly during the past week. Activity in the retail trade has not yet appeared, but schools, colleges, greenhouses and certain public institutions are putting in some coal now, but without discernible effect upon the market.

The Pittsburgh market is as dull as ever. Production is light, and much of it by consumers or by strip mines. There is a little trade in high-grade gas coal, but not much even of that. Local consumption is absorbing only a small percentage of the district's producing capacity. The Connellsville region, with its lower wages, has been making strenuous efforts to get coal business, but without much success.

A general feeling among operators in the central Pennsylvania bituminous field is that the bottom of production and prices has been reached, although not much improvement is expected before August. Production for the week ending July 12 was 10,930 carloads, against 8,291 for the previous week, which included the Fourth of July holiday.

The coal situation at Buffalo does not show much change. Increased orders for steel manufactures are reported but no general business revival is in sight. In some quarters it is asserted that the depression has been overstated and that it will not go any further.

The Toronto market is very quiet, with but little demand for anthracite and less for soft coal. The yards are well stocked in anticipation of fall requirements, but few consumers are laying in stocks and business is less active than at this season last year.

### New England Market Nearly Lifeless

In New England the market for steam coal is almost lifeless. Mills are closing down for weeks at a time, often with no date set for opening, and the trade generally is able to do little more than mark time. The few venturesome shippers who still try to force coal on this reluctant market learn to their cost that it is nearly to the saturation point.

At Hampton Roads the accumulations are moderate, due to a conservative policy on the part of most of the agencies, but quotations are in no wise improved. There is a fair movement off-shore, and this together with coastwise contracts is furnishing outlet for perhaps about a third of what would normally be considered light output.

At Providence, Boston and Portland, for inland delivery, \$5.65@5.75 is still quoted per gross ton on cars, but it is acknowledged that \$5.50 is about the top figure that can be realized on anything exceeding one or two-car lots. This situation effectually shuts out rail coal from territory at all accessible from tidewater, and aside from the few specialties there is practically nothing doing on Pennsylvania coals except in the area around the Connecticut River.

Via the New York and Philadelphia piers there is only a light tonnage moving from the central Pennsylvania districts. Here, too, the bulk of the coal placed is for special uses and is hardly an indication that for ordinary grades there would be any demand except at sacrifice prices.

### Buyers Scarce in Atlantic Seaboard Markets

The New York market drags. Except when bargains may be picked up, buyers are keeping under cover unless it is absolutely necessary for them to get coal. Contracting by public institutions and large consumers has been practically completed save possibly for small lots. An instance of the latter occurred last week when bids were opened for furnishing and delivering alongside for the U. S. Appraiser's Warehouse in New York of 500 gross tons of low-volatile high-grade soft coal. The low bid received was \$4.29 per ton f.a.s., or on a basis of about \$1.16 net ton. f.o.b. mine. Local houses reported a slightly

increased demand for slack and a consequent bettering of quotations. Demand for coke continue quiet.

Outside of an increase in inquiries, there is nothing to indicate that the real buying movement is under way in Philadelphia. Big power plants are adding to their reserves, but are striving to get even lower than current market quotations. The railroads continue to stay out of the market and prospects are not bright yet as to when they will be ready for extra tonnage. Things are a bit better at tide, but bunkering is about as usual. Spot prices are unchanged.

Baltimore notes a strengthening line of inquiry for future deliveries. This is not so marked as to cause any excitement in the trade, but it does give promise of a slow but sure betterment over the midsummer period. There is a general impression here that industrial depression, and with it the slow-down in demand for coal, has about hit bottom, and that from now on a flood tide will begin. The export coal situation in Baltimore shows a decided improvement for the first fifteen days of July as compared to the same period of June.

The Birmingham market remains painfully dull and quiet, but hopeful, though there is no evidence on which to base an early improvement. Industrial conditions are anything but satisfactory, and the coal consumption from this source has been scaled down to a very low point. Spot business is negligible, and deliveries against contracts are on a minimum basis.

### Summer Lull Settles Over Hard-Coal Trade

Demand for domestic hard coals is far from active in the New York market. Straight lots of independent stove coal continue to bring about 25c. more than when taken with any other size, but the activity of the market ends there. Egg coal is not as long as chestnut and for that reason is quoted by some shippers at slightly higher figures than the latter size. Recent cuts in production have had no apparent effect on the local situation. Retail dealers seem to be in good shape to meet all immediate requirements. The larger companies do not have any trouble moving their domestic coals, with the exception of pea, which is accumulating with both "regulars" and "independents." Some of the latter, it is reported, are insisting upon buyers taking a proportionate share of pea with the larger coals. Trouble is experienced in moving the steam coals. Demand is dull and only the better grades of independent product are bringing anything like company schedules.

Retail yards at Philadelphia are quite full of coal of all sizes, including stove. Nut has become particularly sluggish, a few of the smaller independent shippers offering it off price. Pea coal is becoming much easier and egg also has eased off. Steam sizes are doing the most to unsettle the market, for inability to move this coal is clogging the tracks at the collieries.

The hard-coal situation at Baltimore is exceptionally dull. The raise in retail prices probably halted some ordering, and there may be delay over August, as the public is figuring that there will be no further advance Sept. 1. More coal is now being released to Baltimore by mine connections.

## Foreign Market And Export News

### British Market Quiet and Irregular; Output Drops to 4,988,000 Tons

The Welsh coal market is quiet and irregular, the tone being not quite so healthy as it was last week. Stocks all round are heavy and prices are weak. Foreign buyers have filled their immediate needs and are withholding orders for future delivery until exchange settles a bit. There also is difficulty in obtaining shipping because the combination of freights on a pre-war basis and expenses about double means that ship owners cannot operate their vessels and make a profit at the same time. In consequence many ships are laid up, and several coaling berths in the South Wales ports are empty on that account. The cheaper prices of the North of England coal also are a handicap in obtaining new business.

The Newcastle market is very depressed and nothing has occurred to brighten the future. Most of the collieries are working hand to mouth.

The Naples gas works has contracted for 36,000 tons of Newcastle gas coal for delivery from July to December, and the Palermo gas works for 10,000 tons of the best Durham coal for delivery in August and September on the basis of current quotations.

A special cable to *Coal Age* states that the production of coal by British mines during the week ended July 5 totaled 4,988,000 tons, according to the official reports. This compares with an output of 5,170,000 tons during the week ended June 28.

### Hampton Roads Looking Up; Foreign Movement Slow

Slight improvement is noted in the movement at Hampton Roads, the volume of business at the piers showing an increase and the vessels reported due for cargo also being on the upward trend. Coastwise business is holding its own, bunkers are fair, but foreign movement appears to have slumped.

The tone of the market is not distinctly firmer, though it has not weakened from a week ago. Prices remain about the same, and supplies are on the increase. The trade, generally, is sitting tight, awaiting whatever the natural channels of business may bring.

### French Market Shows Notable Stability and Firmness

Stability and firmness are outstanding features of the French coal market. With a good but not extraordinary demand, the current of orders is sufficient to absorb the output of industrial coals and the household fuel situation is satisfactory.

The Nord and Pas-de-Calais collieries have agreed to extend until Sept. 30—and possibly until Dec. 31—the wage increases recently granted. Prices therefore remain unaltered, save for the 0.20 fr. per ton extra charge consequent on the application of the supplementary taxes voted by Parliament.

In order to increase the marketing of ovoids and briquets, which are rather neglected at this time of the year, the northern coal fields are giving summer rebates of 8 fr. on the price of these fuels; these reduced prices will remain effective probably until Sept. 15.—The Belgian collieries have decided to take similar steps.

There is little activity in British coals at the present time, the orders for anthracites having practically completely disappeared.

At its meeting on June 24, the Coal Consultative Committee approved the abrogation of export restrictions and the decree will be published shortly.

During the month of June the O. R. C. A. was supplied with 417,806 tons of coke, or a daily average of 13,900 tons. The price of coke remains at 150.75 fr. for July.

The new Dusseldorf accord as of

July 1 includes the clauses of the agreement signed April 15 but with the following modifications: Reduction of the coal tax to 0.75 mark per ton; reduction of the licenses and allowances taxes to half of their former rate; tax on the circulation of byproducts reduced to 1 per cent; delivery of byproducts limited to 10 per cent benzol, 8 per cent sulphate of ammonia, 6 per cent pitch, 8 per cent other byproducts. The first three reductions are retroactive to June 16. The deliveries corresponding to the period of the strike (May 1 to June 7 inclusive) will be reduced to 27 per cent of the effective production during the same period of time.

## News Items From Field and Trade

### ALABAMA

A new mine is being opened by Olin Goodwin near Dora, Walker County, a good force now being employed in the development work.

J. S. Chalmers has been appointed superintendent of the Nauvoo operations of the Monro-Warrior Coal & Coke Co., succeeding Chas. Blanchard.

The Alabama Company is constructing a 2,400-ton Montgomery coal washer at its new opening at Lewisburg, and work of sinking the slope is progressing satisfactorily.

The Ensley-Southern Ry., formerly operated under the management of the Southern Ry. system, has been placed in the hands of a receiver by the federal courts on application of the latter road. The Ensley Southern, which operates a short mileage serving coal mines in the Walker County field and Birmingham, on the Warrior River, has been in financial straits for some time. A. B. Aldridge, president of the Stith Coal Co., was appointed receiver by the court, with instructions to continue the operation of the line for the present.

The 10 per cent reduction of wages announced July 10 by the Woodward Iron Co., Birmingham, affected all employees except common labor, including coal miners. Although no official announcements have been made, one or more other companies have made or will make wage reductions, it is reported. The Woodward company produces little or no coal for the commercial market and none for the domestic trade, the output being coked for its own furnace use. The reduction was due to the selling price of iron dropping below cost.

### ILLINOIS

The McLean County Coal Co., of Bloomington, has sold its office building, at the southwest corner of Main and Market Street, in that city, to W. J. Moran, of Peoria.

John Hayes has resigned as mine manager of the Kathleen mine of the Union Colliery Co. at Dowell, and has been succeeded by Edw. Leming, formerly assistant at the same mine. John Meyers is now connected with the company as an assistant mine manager.

During the first six months of 1924 the 81 mines in the Fifth and Ninth districts of Illinois—the region immediately east of St. Louis, Mo.—mined 1,482,192 tons of coal less than during the same period the year before. The total production for the 1924 period was 5,312,592 tons. The total working

time was but 25,072 hours, as compared with 37,586 hours in the 1923 period. This represents a net average of only 52 working hours a month for each mine during 1924. In June 49 mines were idle and the other 32 averaged only 37 per cent running time.

### INDIANA

The mule barn at the Interstate mine, near Clinton, was burned recently and only two of twenty-two mules were saved. The origin of the fire is not known. The mine had been working about four days a week and had expected to start on a more extensive scale.

Edwin D. Logsdon, president of the Knox Consolidated Coal Co., of Indianapolis, has been elected a member of the board of directors of the Fletcher American National Bank, one of the strongest financial institutions in Indiana. He succeeds the late Crawford Fairbanks, of Terre Haute, well known to the coal trade.

A crowd estimated at 10,000 attended the recent eighth annual state first-aid meet at Princeton. Twenty-one teams competed. First place was won by the Peerless mine of the Templeton Coal Co., from Sullivan, and second by the Clinton Coal Co., of Clinton. A banquet was held in the evening. John L. Lewis, International president of the United Mine Workers, and other union officials spoke. The meet was under the direction, as usual, of the Joseph A. Holmes Mine Safety Association.

### KANSAS

August Dorchy, deposed vice-president of District 14 of the United Mine Workers, will appeal to the U. S. Supreme Court from the Kansas Supreme Court's decision that he must complete a six-months' jail sentence in Cherokee County and pay a \$500 fine. Dorchy along with Alex. Howat was convicted and sentenced for calling a mine strike in violation of the Industrial Court law. The U. S. Supreme Court decided the wage-fixing sections of the law were unconstitutional. The Kansas court held that the anti-strike section is valid and that therefore Dorchy is still a prisoner.

### KENTUCKY

Attorneys for the Harlan Coal Co., Louisville, probably will make a motion for a new trial in a case lost a few days ago against the Wheeler Coal Co., in Judge Gordon's court at Louisville.

The Harlan company filed suit in 1920, alleging that under a contract made in 1919 the company was to acquire the entire output of the Wheeler company mines, and that the Harlan company was damaged to the extent of \$75,000 by failure of defendants to abide by its contract.

The Elkhorn Coal Corporation, Fleming, is recalling its old employees following a resumption of its mines at Fleming, Haymond and Hemphill on a full-time basis.

The largest contracts announced for some time were reported from Frankfort, July 15, when the State Board of Charities and Corrections placed contracts on nut and slack, or steam coal for use in the various state institutions. These contracts call for 646 cars, or approximately 32,300 tons, based on cars of 50 tons capacity, and prices average about 75c. a ton under prices paid last year, or a saving of about \$24,225 to the state. Prices of \$1.10 a ton were paid on eastern Kentucky coal at the mines, and from \$1 to \$1.25 for western Kentucky on short hauls from western Kentucky mines.

### NEW YORK

The Harbor Coaling Corporation of New York City, a Delaware corporation, has been granted permission to increase its capital from \$5,000 to \$25,000.

R. M. Bryan, who for more than 17 years was the eastern manager for *The Black Diamond*, has resigned to assume charge of veterans' tours to France inaugurated by the United States Lines of government-owned steamships.

The Harbor Coaling Corporation, 10 Bridge Street, New York, has leased from the Lehigh Valley R.R. the latter's rebuilt National dock, on the west shore of the Hudson River at Communipaw, N. J., for ten years with privilege of renewal.

### NORTH DAKOTA

Fire of unknown origin destroyed the tippie and hoisting shaft of the Archibald mine, near Foxholm, July 10, causing damage estimated at \$10,000. Only one man was in the mine at the time the fire was discovered, and he was hoisted to safety by another employee.

### OHIO

Although coal mines in the eastern and north central region of Ohio operated 65 per cent of the full-time capacity during the month of June,

only two fatal accidents were reported, it was announced recently. Inspections were made of 130 mines, or 55 more than during the month of May.

## OKLAHOMA

Chas. N. Gould was appointed director of the Oklahoma Geological Survey at Norman, beginning July 1. Dr. Gould organized the Survey and was its first director in 1908. He formulated its earlier policies and resigned in 1911 to enter consulting work. Dr. D. W. Ohern was appointed his successor. Three years later, when he resigned, C. W. Shannon was placed in charge. The Survey appropriations were vetoed a year ago by the then Governor Walton. In the interim Prof. Chas. E. Decker, of the State University, has been acting custodian. The special session of the Legislature made a small appropriation for the maintenance of the Survey and placed it under the control of the Board of Regents of the university. Dr. Gould announces as his policy the development of Oklahoma's natural resources and solicits the co-operation of every citizen interested in the development of these dormant resources.

## PENNSYLVANIA

The U. S. Bureau of Mines has opened a branch station devoted to coal-mining research at 801 Coal Exchange Building, Wilkes-Barre. D. C. Ashmead is in charge.

Walter Thayer has been appointed coal traffic manager of the Eastern region of the Pennsylvania R.R. system, according to an announcement by Geo. D. Ogden, traffic manager. Mr. Thayer's headquarters will be at Philadelphia.

C. Larry Marlatt, of North Scranton, has been named as general superintendent of the Mount Jessup & Bald Mountain Coal Co., according to an announcement made in New York by William H. Grady, general manager

for Whitney & Kemmerer, who own the mine. Mr. Marlatt had for the past eighteen years been with the Hudson Coal Co., starting on the surveying corps in 1906, and working up through the engineering department and production department.

At Paxinos, eight miles north of Shamokin, a large creek washery breaker owned by W. A. Sees, of Wilkes-Barre, was blown over and collapsed on the state highway on June 25 during a severe wind storm.

The Pittsburgh & Eastern Coal Co., of Cleveland, is erecting a new and larger tippie at its Cherry Valley mine, in Washington County.

With a program of \$20,000,000 in improvements being outlined for the Johnstown plant of the Bethlehem Steel Corporation, extra power will be needed and work has been started on clearing the ground for the erection of a large power plant in Franklin. Five new mills will be added to the Gautier plant and work on clearing old buildings and dwelling houses from the land they will occupy has been started.

Coal companies in the Gallitzin fire district, which takes in large portions of Cambria County, planted 900,000 forest trees this year. Many of the coal companies are buying idle farm land and planting forest trees. The foresters in this district have set the goal at five million trees, in order to reforest the denuded lands in the coal fields. Assistant District Forester T. I. Shirley, of Johnstown, is giving all possible assistance to companies and individuals reforesting vacant land.

The H. C. Frick Coke Co. is now using the five-mile belt conveyor system recently installed to convey the coal underground from the Colonial Nos. 2, 3 and 4 mines at Grindstone, Rows Run and Smock to the Monongahela River near Fayette City through the old Alice mine main entry, acquired from the Pittsburgh Coal Co. for that purpose. The coal is fed on to the belt at the inner end by a 35-car revolving

dump furnished by the Car Dumper & Equipment Co., of Chicago, and at the outer end is loaded in barges in the river, and taken mostly to the by-product ovens of the Carnegie Steel Co. at Clairton.

Attorneys acting for David Lloyd, former Glen Alden Coal Co. superintendent, purchased the Oak Run Coal Co. at Archibald, for \$50,100, at a receiver's sale in the Lackawanna County court house, Scranton, July 18. Several interests bid for the property. The Oak Run mine, a slope operation on the mountain east of Archibald, formerly was known as the Wachna mine. Coal taken from lands owned by the John P. Farnham estate have been transported by aerial tramway down the mountain 3,300 ft. to the breaker. The company went bankrupt several months ago. David R. Humphrey, of Peckville, was president, and John J. Owens, former Assistant District Attorney of Lackawanna County, was secretary-treasurer.

Five to six hundred men have been idle at Nant-y-Glo, Cambria County, since July 15, according to word received by Superintendent John W. Harrison of the Heisley Coal Co. The Heisley mines have been working steady for two months, loading more than 40,000 tons of coal during May and June. The company contemplated a shutdown in April but continued in the hope that conditions would improve. The reason confided to the superintendent by officials of the company is that the company is unable to compete with the non-union mines. It was intimated that if the men would accept the 1917 scale it might be possible to keep the operations working at least a part of the time.

School boards in a half dozen cities and boroughs of the anthracite region are giving consideration to the installation of small-sized coal burning grates in the heating plants of the school buildings under their jurisdiction. The action is believed to be a result of the campaign conducted by anthracite producers, urging the use of small size fuel. Among the school directors contemplating the change are those of Hazleton, Carbondale, Olyphant, and other places.

Judge Koch issued a decree of foreclosure recently in the case against the Schuylkill Valley Coal Co., of Port Carbon, brought by the bondholders, represented by a Pottsville bank. The decree will enable the bondholders to reopen the operation, which has been closed for months. The company has had financial difficulties for months past, and employees, unable to collect back pay, started legal proceedings. The claims, amounting to \$24,000, have now been paid and the mine has been cleared of water and is ready for operation.

There were eighty-three fewer fatal accidents in Pennsylvania during the first six months of 1924 than during the same period of 1923, according to Secretary of Mines, Joseph J. Walsh. During the first six months of this year 412 miners lost their lives in accidents while 495 miners were killed in the first six months of last year. The decrease in the number of deaths was divided about

Courtesy U. S. Distributing Corp.

### Mine Cars on Way to Tippie at Acme Mine

It can be seen by the foliage on the hill in the rear that this mine is in the far West. It is located in Sheridan County, Wyoming, and is the property of the Sheridan-Wyoming Coal Co.

evenly between the anthracite and the bituminous fields. A total of 248 miners was killed in the anthracite mines during the past six months as compared with 289 in 1923, or a decrease of 41 deaths. In the bituminous field 164 men were killed in accidents during the first half of 1924 as contrasted with 206 in 1923, a drop of 42 deaths. The decrease represented 14 per cent of the former fatalities in the anthracite field and 20 per cent of the 1923 totals in the bituminous mines.

## UTAH

Utah's coal output for June amounted to 261,975 tons, compared with 333,230 tons for the same month last year. In 1923 the figures were 337,629. June 1921 showed only 220,941 tons, but the previous year showed an output of 531,600 tons, or more than twice as much as June, 1924.

## WASHINGTON, D. C.

A decision in the mine-rating case is not expected before autumn. Fully a month must be allowed for the delays incident to the vacation period. The rules covering car distribution are closely related with the assigned-car case. The postponement of the effective date in the latter proceeding until Nov. 1 is thought to indicate that the Interstate Commerce Commission hopes to be able to hand down that decision prior to that date. It is expected that each of these decisions will be handed down at about the same time.

## WEST VIRGINIA

A state first-aid meet will be held at the State Fair Grounds at Wheeling on Sept. 4 at 9 a.m. The contests are open to teams of all coal companies in the state. The winners will be declared state champions and awarded the cup, which is at present held by the Thomas team of the Davis Coal & Coke Co.

The following coal companies have filed certificates of dissolution with the Secretary of State of West Virginia: Huntington Coal Sales Co., Acme-Eagle Coal Co., Fielder-Davis Fuel Co., Greenmount Fuel Co., Jarvis Coal Co., Rich Block Coal Co., Hutton-Beal Coal Co., New Pocahontas Coal Co., Harry's Branch Coal & Coke Co., D. K. C. Coal Co., Hendricks Coal Co., Coolidge Coal Co., and the Imperial Coal Sales Co., which was dissolved by deed of sale.

Coal companies recently dissolved and the charters of which have been surrendered include the Miami Coal & Coke Co., of Moundsville, and the Greenmount Fuel Co., of Morgantown.

The Lillybrook Coal Co., at Sullivan, near Beckley, Raleigh County, is putting the finishing touches to a modern mine and expects to start operating about Sept. 1. Two seams of coal will be worked at this mine, the Beckley seam by drift mining and one of the Pocahontas seams by shaft. An addition was made to the town. The tipple is of steel, having shaker screens and

picking tables, and a semi-automatic substation is being completed which can be set to divert most of the power to the workings in the seam yielding the coal most desired at any particular time. This arrangement will halt only one operation in case of overloading.

Scott's Run, in Monongalia County, was the scene of a recent pitched battle between different factions of the United Mine Workers over the election of a checkweighman. The trouble started in the union hall, but the miners went into the open to settle the dispute. One miner, Joe Susac, unable to obtain recognition and to gain the floor, wielded a knife to cut his way to recognition. In a minute rocks and bricks were flying through the air and members of the contending factions were flaying each other with pickhandles. When Sheriff Yost arrived Mike Rockvitch had been cut about the legs, arms and body and Joe Susac was still in action. Joe and Pete Rockvitch were arrested and put in jail. In the meantime there was no agreement on a checkweighman.

The Hudson Coal Co., of Clarksburg, recently entered into an arrangement with the Metropolitan Life Insurance Co. to insure the lives of its employees through the medium of a group policy, under the terms of which no medical examination is required, while supplementary to the provisions of the policy the workers are entitled to the services of Metropolitan nurses in case of sickness or injury. They also will receive at stated periods health pamphlets issued by the insurance company. The total insurance amounts to \$136,000, the protection for individuals ranging from \$1,000 to \$1,500. In the case of sickness or injury \$10 a week is paid for twenty-six weeks.

## WISCONSIN

The Great Lakes Coal & Dock Co. has leased the docks once occupied by the Central Coal Co. on Canal Street, near the Twenty-seventh Street Viaduct, in Milwaukee, and is now storing coal upon it. About 15 cargoes have been received by the company thus far this season.

## WYOMING

Clyde N. Fisher, cashier of the Gunn-Quealy Coal Co., Rock Springs, Wyo., who disappeared July 15 with the semi-monthly pay roll of the company, was shot and fatally wounded early the next day by J. Walker, mine foreman and friend of Fisher. He died a few hours later without making a statement. Search of the vicinity where the shooting occurred revealed a caché of food, water and blankets, also the entire payroll, which totaled more than \$6,000.

Wyoming may soon have a new railroad that will open up more coal lands in the southwestern quarter of the state. The Wyoming & Colorado Shortline has been incorporated by Colorado and Wyoming men and has now applied to the Interstate Commerce Commission for the right to construct a 380-mile line from Casper

southwest to the state line. Oil, timber and cattle probably will be the principal freight produced along the new road.

## CANADA

The Gibson Collieries, Ltd., of Drumheller, Alberta, has been adjudged bankrupt and a receivership order issued appointing the Security Trust Co., Ltd., custodian.

Supplementary estimates passed in the House of Commons at Ottawa contain an item of \$200,000 to provide for transportation of Canadian coal from Alberta and Nova Scotia to central Canada by the Canadian railways.

In order to encourage the shipment of coal from Alberta to the provinces of Ontario and Quebec the Dominion government has appropriated \$200,000, for payments to railway companies to make up losses which may be incurred by them in granting reduced freight rates. This policy is a concession to the demands made by several cities of central Canada.

The movement for negotiation of a separate agreement between Gladstone Local of the miners union, at Fernie, B. C., and the management of the Crows Nest Pass Coal Co., which for some days promised a settlement of the strike in the eastern British Columbia section of District No. 18, U. M. W. A., has been broken. District President Sherman visited Fernie on learning of the development. Addressing a mass meeting of the miners of Fernie, Michel and Coal Creek he promised immediate additional relief to the extent of \$3,000 and that a meeting of the International Executive Board was to be held at Indianapolis to discuss the situation in District 18. Finally they resolved to stick out for the Jacksonville agreement. Then they declined the company's offer based on a 12 per cent higher rate of wages than that now in effect in the Vancouver Island Coal Mines.

## Trade Literature

**The Buffalo Forge Co.,** Buffalo, N. Y., has issued a folder designated as Form 1875 describing the operation and use of the Buffalo coal burner for burning junior grades of coal.

**The Hoar Shovel.** Hoar Shovel Co., Duluth, Minn. Pp. 24; 7½x10½ in.; illustrated. The use of this shovel for mucking is described and its operating costs are given. The shovel is shown working both on the surface and underground.

**Heine Bent-Tube Boilers.** Heine Boiler Co., St. Louis, Mo. Bulletin 54. Pp. 25; 8x11 in.; illustrated. Describes the general design, circulation, construction, supports, trimmings and accessories of the V-type boilers.

**The Detroit Electric Furnace Co.,** Detroit, Mich., has issued a booklet on **Brass Melting.** It tells how the electric furnace is a factor of ever-increasing value in brass melting; it enumerates the economies effected by the electric furnace and then shows how complete control of analysis, color, texture and homogeneity of the alloy is secured through the electric furnace. The bulletin is known as No. 41.

**Air Filters for Compressors and Internal Combustion Engines.** Mid West Air Filters, Inc., 100 E. 45th St., New York City. Pp. 24; 8x11 in.; illustrated. Among the advantages claimed for these filters are full efficiency in the operation of compressors and engines, and the equipment depending on them, less oil, longer life and fewer shutdowns. Tables and useful data are included.

## Traffic News

### Commerce Commission Makes Western Coal Rates Decision

The June 9 decision of the Interstate Commerce Commission on what is known as the Western coal rates case has been published. The commission reduces to 40c. its 1923 ruling which fixed a 50c. differential in favor of the Castlegate region over the Rock Springs-Kemmerer region on coal going to points west and north of McCammon, Idaho. It declined, however, to separate the Rock Springs and Kemmerer fields into two rate groups, even though Kemmerer is 85 miles west of Rock Springs. This was because very little Kemmerer coal competes with Utah coal west of McCammon.

The commission withdraws its recent order increasing from 10 and 12c. to 40c. the differential on west-bound coal enjoyed by the Sego mine of the American Fuel Co., about 95 miles east of Castlegate, Utah, over the mines of the Cameo-Faliscade district of Colorado. The old rates are to prevail until the commission makes a decision in No. 13,509.

The establishment of joint rates on Castlegate coal to points in Oregon and Washington on the Northern Pacific, Great Northern, C. M. & St. P. and the Spokane, Portland & Seattle railroads such as apply on the Union Pacific was refused. However, Commissioners McManamy, Aitchison, Eastman, Campbell and Cox, comprising almost a majority of the commission, dissented.

### May Take Northwest Rates To Court for Test

Hints are being given in the all-rail trade that if the recent petition for a rehearing of the case of the dock association against the all-rail carriers fails, there probably will be a move to bring the case into court for a test. The first step would be an injunction to restrain the enforcement of the new rates, which would come shortly before the time for them to become effective—Aug. 21. A temporary injunction doubtless would be issued, which would suspend the rates until the case came up in court, which might take several months. The railroads affected seem to be proceeding with the preparation of the new tariffs, and do not seem inclined to offer any objection to increased revenue rates.

### Want Joint Rates to Frankfort From All Kentucky Fields

The Frankfort (Ky.) Chamber of Commerce and various coal concerns of that city have jointly petitioned the Kentucky State Railroad Commission to require the Louisville & Nashville R.R. and Frankfort & Cincinnati R.R. to establish joint rates with other roads from all coal fields of the state to Frankfort, the complaint charging that there are no joint rates on coal transported and delivered at Frankfort, and that coal handlers or consumers are compelled to take coal from mines on lines of the Louisville & Nashville.

## Obituary

Business troubles led W. J. Elliott, of Princeton, W. Va., treasurer of the Wysong-McCoy Coal Co., to take his own life. His wife found him dead in his office, a pistol on the floor nearby. Mr. Elliott was formerly cashier of the Bank of Matoaka, president of the Rock District Board of Education, Sheriff of Mercer County from 1916 to 1920 and cashier of the First National Bank of Princeton.

Mrs. F. A. Reed, mother of Geo. W. Reed, vice-president of the Peabody Coal Co., in charge of sales, died suddenly at her home Wednesday, July 16, 1924. The funeral was held Friday the 18th from the home of her son, 7136 Luella Ave., Chicago.

Reese E. Evans, age 67, secretary of the Bessemer Coal, Iron & Land Co., of Bessemer, Ala., died at Biloxi, Miss., July 13 after an illness of long duration. Mr. Evans had been in the Birmingham district for the past forty years and was widely known and possessed a host of friends who will mourn his passing.

## New Companies

The Gray Coal Co., of Gray, Ky., capital \$10,000, has recently been chartered by J. T. Gray, Mattie Gray and J. H. Gray.

The Pike County Collieries Co., of Danville, Ill., capitalized at \$262,500 to own, lease and operate coal mines, has been authorized to do business in Indiana as a foreign corporation, with C. F. Shannon, of Petersburg, Ind., as state agent.

The Standard Fourth Vein Coal Co. has been organized at Linton, Ind., by G. B. Taylor, A. G. Schneiderhelm, C. F. Sherrard, F. J. Schneiderhelm and Pearlle Poole to mine coal and other minerals. The company's capital is 5,000 shares of no par value.

The following bituminous coal companies have been incorporated in Pennsylvania: Windber Coal Mining Co., Johnstown, capital, \$25,000; incorporators, Irving L. Camp, Wayne Street, Westmont, Johnstown, treasurer; C. E. Schooley, Johnstown, and G. C. Trueaux, Windber. Punxiana Coal & Coke Co., Indiana; capital, \$800,000; this company was formed by the merging of the Punxiana Coal & Coke Co. and the Meco Coal Co. H. A. Snyder, Indiana, is treasurer, and the company's purpose is to mine coal and manufacture coke.

## Coming Meetings

Western Canada Fuel Association. Convention Aug. 5 and 6, 1924, Brandon, Manitoba, Can. Secretary, W. H. Morrison, Winnipeg, Man., Can.

Rocky Mountain Coal Mining Institute. Summer meeting, Aug. 7-9, Rock Springs, Wyo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

New York State Coal Merchants Association, Inc., 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters Churchill Hall. Executive Secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

American Chemical Society. Fall convention Sept. 8-11, 1924, at Ithaca, N. Y. Secretary Gas and Fuel Section, O. O. Malleis, the Koppers Co., Pittsburgh, Pa.

Oklahoma Coal Operators' Association. Annual meeting Sept. 11, 1924, McAlester, Okla. Secretary, A. C. Casey, McAlester, Okla.

Association of Iron and Steel Electrical Engineers. Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

National Safety Council. Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

American Institute of Mining and Metallurgical Engineers. Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

American Institute of Electrical Engineers. Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Pipe Fittings for Electrical Switching Equipment

Structural interchangeable pipe fittings, designed for use with common wrought-iron or steel pipe in the erection of outdoor or indoor electrical switching equipment, recently have been put on the market by the Westinghouse Electric and Manufacturing Co. Though designed primarily for electrical installations, they are equally available for the construction of racks, railings and bench or table frames, electric sign structures, playground apparatus and dairy stable stanchions.

Pipe is a convenient material for structural work of this kind as it is light for its strength, has a symmetrical cross section which resists bending equally well in any direction, and can be cut easily and rapidly with inexpensive tools by inexperienced labor. The fittings are more adaptable

### Interchangeable Fittings for all Kinds of Pipe Framing

(1) Four-way or side-outlet tee; (2) Another side-outlet tee; (3) Six-way fitting with double 45-deg. brace showing great adaptability of fittings.

than those designed for ordinary plumbing. They are made of high-grade malleable iron with a minimum tensile strength of 50,000 lb. per square inch, are light in weight, compact and neat in appearance.

The only tools necessary to erect a structure with these fittings are a pipe vise and cutter and an open-end or socket wrench for each of the two sizes of bolts used. Changes in and additions to such a structure are made with facility. The principal feature of the design of the new fitting is a ribbed yoke which clamps over the pipe and is attached with heavy carriage bolts to the other unit part. Various other units consist of two or more yokes cast in a single piece through connecting webs. As the bolt spacings are uniform, parts designed for a certain size pipe are interchangeable with all others for that size. When the fittings are bolted they yield slightly, due to the malleable characteristic of the iron, until they fit the pipe perfectly.

Ordinary carriage bolts galvanized

by the hot-dip process, are used, the square shank under the head fitting into the square hole in the fitting, so that assembly can be made with a single wrench. The fittings are designed for two standard pipe sizes, 1½ in. and 2 in., and for a combination of these sizes, with a few fittings of ¾, 1 and 1½ in. size for light switchboard frames and for clamping insulators to pipe frames. They have a black gloss baked finish for indoor use or are galvanized for outdoor installations. With galvanized pipe and fittings, an outdoor structure which will resist weather conditions for years without maintenance cost can be provided.

### Elevates and Transports Loads

A storage-battery elevating truck and tractor by which a load can be picked from the floor or placed upon it, the loading platform requiring little clearance, is being manufactured by the Elwell-Parker Electric Co., Cleveland.

The elevator head at the forward end may be equipped with two or more forks at the floor line, 1 to 2 in. thick and of proper spacing and length to handle bales, boxes or barrels, car wheels, receptacles or the like. When fitted with a pair of arms 18 in. above the floor, barrels may be handled and when equipped with a single horizontal

**Battery-Operated Elevating Truck**

Equipped so as to be able to handle almost any kind of load this new machine is both an elevating truck and tractor. Automatic safety devices make it easy to operate.

shaft the machine may be used in handling coils or wheels.

The machine is made up of the company's standard tractor-type, hot-riveted tractor frame with battery compartment and hinged cover. The operator's seat is located forward to provide an unobstructed view of the movement of the elevator. The seat is arranged to actuate the electric circuit breaker connecting the battery to the controller located in a separate compartment. The circuit breaker closes only when controller drum is in off position and the controller comes to full stop when reversing. A brake pedal with heel-operated latch is located on the footboard, actuating dual contracting shoes on a 7-in. brake drum.

The drive axle is located at the ele-

vator or front end to assure traction by under all conditions of loading. The wheel base is short, and all four wheels equipped with 7-in. double-row ball bearings and 20 x 3½ in. tires. The hoist unit, which is mounted immediately in front of the operator, consists of an inclosed motor and electric brake. The motor drives a single-grooved drum through a bevel and worm gear reduction inclosed in an oil-filled housing. This drum winds a ¾-in. plow-steel cable. The cable passes over a sheave at the top of the elevator uprights to the traveling elevator head, which is provided with special attachments to support the load. The elevator head is guided by four rollers running inside the upright channels. The hoist motor is operated through a controller at the right of the driver's seat.

### Electric Screwdriver Revolves Only When Pressure Is Applied

A portable electric screwdriver and an automatic lag-screw driver, a feature of which is an automatic overload safety device which shuts off the current when the motor runs beyond its rated capacity, preventing damage to the motor, have been placed on the market by the John Steptoe Co., Cincinnati. These tools are part of the line formerly built by the Automatic Electrical Co., Cincinnati, the manufacturing and selling rights of which the Steptoe company has recently acquired.

The electric screwdriver weighs only 5 lb. and may be held in one hand while inserting or removing screws, the other hand being free to hold the work in position. It is claimed that No. 16 screws 3 in. long may be driven into hard yellow pine without first drilling a hole. By placing a bit on both sides the tool may be used for driving or withdrawing screws. The tool runs at 250 r.p.m., and is arranged so that it will not revolve until the bit is placed in the screw slot and a downward pressure applied that engages the positive driving clutch. Although the aluminum pistol grip is provided as regular equipment, it readily may be removed.

The motor, which is of special design, runs at 10,000 r.p.m., and is reduced to the spindle speed through a gear and worm drive. The motor is air-cooled

**Power Screw Driver**

Even the screw driver has had to be electrically driven. The tool that turns the trick weighs only 5 lb. and can be held in one hand.

by a fan, which is machined from a heavy bronze casting. Ball bearings are employed for the armature and gear shafts. The casing is of aluminum. An automatic overload safety device is provided as part of the regular equipment. The conductor cord is reinforced at the machine with heavy rubber hose and is attached to a terminal block, to prevent strain on the motor by pull on the cord.

The machine is rated to drive any size screw that can be driven by a hand brace. The automatic lag-screw driver may be used to advantage in putting up countershafts and in lagging machines to platforms. This machine weighs 30 lb.

### Mine Tie That Resists Creep

Inasmuch as transportation is an important part of coal production it is not strange that many improvements in track construction and materials should originate at the mines. Metallic ties have long been known and used both for mine and railroad tracks. One of the chief disadvantages of such ties, however, has been their comparatively slight hold on the roadbed and their consequent tendency to creep.

In order to obviate this difficulty, William M. Riggins, of Lynch, Ky., has devised the tie shown in the accompanying illustration and for which application for letters patent has been made. As may be seen from this drawing this tie does not differ materially from other devices of like nature except that at each side of each rail a plate or anti-creeper is secured to the sides of the tie. This plate is so formed that it forces its way downward into the roadbed and resists whatever tendency toward creep may be developed by the action of the locomotives and trips that pass over the track.

**Lest the Ties Bunch**

Like creepers on one's shoes are the creepers on Mr. Riggins' steel tie, only one assists and the other resists creeping.

### Said to Treble the Life of Woven-Wire Fencing

A new process of galvanizing that trebles the life of woven-wire fence has been announced by the Page Steel & Wire Co., of Bridgeport, Conn. The new method is called "galvanizing after weaving." A protecting coat of zinc five times heavier than that on ordinary galvanized fence is applied to the fabricated wire. Formerly the wire of which fence was made was first galvanized and then woven into fence and, as many mechanical operations were performed, the thickness of the zinc coating was definitely limited.

In the "galvanizing after weaving" method, the mechanical operations are all performed first, and the fabric is then galvanized, thus permitting the application of a "super-heavy" coating of zinc. In service tests, wire bearing the thickness of coating that is applied by the new method has successfully withstood exposure in New England for more than seven years.

## Functioning Badly

**W** E COAL MEN are in grave danger of being thrust from our long held place as the worst functioning industry. The U. S. Department of Commerce has published a summary of the report and recommendations of the committee appointed by the President's Conference on Unemployment. It has to do with seasonal operation in the construction industries. "The committee reports," says Mr. Hoover in a preface, "that building trades workers in most American cities are employed less than three-quarters of a year. As a result the trades are fully employed for only three to five months." At that we are not sure that the palm for bad functioning rests with the construction industry. It has some close rivals, and there are some industries that do not even attempt to rival it in its inactivity, but these are so casual that they are not held to account.

## Who Are Your Favorites?

**E** VERY MANAGER has his favorites—the men he believes assist him most greatly in getting out cheap and good coal, but unless he has a close record of performances, a knowledge of actual and proper unit costs, he is liable to be led astray by a glib tongue, a confident manner and personal preferences. Most managers do not know enough about what are proper costs and what are actual costs at any mines for them to form any correct judgment.

In consequence they do not know to whom to award praise, to whom to give an increase of salary, whom to keep and whom to let out. Furthermore the company officials knowing that honor is not weighed in the balance, that salaries are based on guesswork, that jobs are dependent on mere prejudice resent such unfair management. But if accomplishment is measured carefully, if costs are matters of general knowledge, the subordinate company officials know that a verdict based on both can, and probably will, be fair and that satisfactory work will be appreciated. They will be explaining when the results are bad and will not wait to be requested to explain. They will recognize the trend of costs as soon as the manager.

## Shifting Fans

**A** PROFITABLE economy in mining is to shift fans from plant to plant to suit the conditions at the various mines. As the workings develop, the equivalent orifice of the mine changes, and the fan will not work economically if that factor of the mine is not equal to the same factor of the fan. Of course, no mine retains for long an equivalent orifice that suits the fan, but there is no economy in continuing to operate ventilating equipment the equivalent orifice of which is greatly different from that of the mine. As the workings get

larger they need another fan and also, in their declining days, as they get smaller they need a fan giving a lower water gage. By shifting fans each mine can get the ventilating unit it needs. It is a job requiring an expert to make the appropriate changes, and an expert is needed to determine just when a change would be economical and when the cost of the change would be less than the economy effected by it. But the relocation of fans affords a possibility of economy not to be overlooked. Where a company has few mines it will be necessary to buy new fans and perhaps to sell the old ones, and even large companies with many mines may find that practice advisable.

So little do some people, who should know better, understand ventilation that they are disposed to criticize a fan because it fails to get as good results when the mine is large as it did in the earlier days when the mine was small. Moreover, there are men to be found who would like to get twice as much air in a mine without a change in the water gage, which is obviously impossible, for the quantity of air the mine will pass varies with the square root of the pressure placed upon it.

## Find a Place for Your Slack

**F**INE coal will continue to be sold at lower prices than lump coal, till place is found for all the slack mined and operators have to crush part of their product. Consequently, operators should bestir themselves to show the advantages of using fine coal in boiler plants. It is advantageous and the public should know it. Instead of lamenting the low cost of slack, bituminous operators should actively promote its use, as the anthracite companies have been promoting the sale of buckwheat.

This is a problem of salesmanship which should be impressed on every man who comes in contact with the backwoods, backward consumer who is still burning run-of-mine under boilers. The railroads should be urged to use stoker-fired equipment, and the domestic consumer should be recommended to use smaller coal, instead of buying lumps and reducing them to dust with a hammer. We all need to be told. Rapid progress is never made unless someone is prepared to deliver the message of better methods and lower costs.

Why leave this to the boiler salesman who does not meet the consumer till the consumer calls him in? If the boiler company's representative tried to sell the better equipment his word would be discounted as a too greatly interested party. In fact the average consumer of mine run never meets the maker of stoker-fired equipment, the maker of the better boilers not being engaged in the selling of the cheaper, less economical types. The salesman of coal can sell the idea better than almost anyone else as he is actually advising that his client buy less and cheaper coal. The boiler man

would be recommending his customer to spend more for boilers than the customer desired and, usually, to scrap the old boilers to buy of him the equipment he advocated. Attacking from that unfortunate angle he could not hope to overcome the buyer's resistance.

### Another—and a Better—World

CARLISLE SPEDDING, a young man about to be put in charge of certain Whitehaven collieries at the beginning of the last century, took a trip to Newcastle-on-Tyne to see how the mines were being operated in the Northumberland collieries. Probably he had economic purposes in view and went principally to find out how to make the Cumberland collieries profitable, but he was nevertheless quite largely interested in safety, as is evidenced by his later introduction of the practice of "coursing," or as we would say, circulating the air through the mine workings.

He also invented the "Spedding Steel Mill" by which in those days, before the introduction of safety lamps, it became customary to light gaseous mines. He learned that a spark produced by friction would not ignite gas, and by revolving a steel wheel against flint he was enabled to obtain a steady stream of sparks that would illuminate, even if uncertainly, the face at which the miner was working, the methane being too slow in combustion to be ignited by so fleeting a source of heat.

But whatever the purpose of his visit, this is true: He had to disguise himself as a miner to get an opportunity to visit the mines, so closely did the owners of one property hold their secrets from the employees of the owners of another though in the same country.

Today we may note with pleasure the World Power Conference held by the same nation with scientists of all the civilized world present and with the notables of that country welcoming the visitors and all contributing freely to that congress the facts regarding their methods of operation. The world indeed has changed—and for the better. Those who doubt that fact kindly take notice. A little more than a century ago, the world in general kept its manufacturing methods so secret that enterprising Englishmen went abroad as workmen to learn what was being done in foreign countries. It will be recalled how many years earlier one of them, Richard Foley, disguised as a fiddler, seeking work, with infinite patience and no little hardships, obtained the secret of the nail-splitting machine then in use only in Sweden. English manufacturers were at that time, at least, equally secretive.

The World Power Conference is only one of many straws showing how the world is changing. Men are more and more traveling, not alone for pleasure and profit of the mind but to learn how to conduct their business. Ideas are no longer buried in one man's mind to die with him. They fructify in every country; they bear seed the world over. The greatest gift that any man can give is not a library of dead books, of histories or of manuscripts that describe the past, but the records of his own contribution to human progress, the new methods that have sprung from his experience, the ideas that his own brain has evolved. The libraries are well, but the record of modern practices is even better and, best of all, even a man of small means often can in this way serve the public better than the man of millions.

### A Superiority Complex

IT IS A SAD commentary upon unionism that most of the local unauthorized strikes occur in the strongest union fields. The latest exhibit worthy of note was the strike at the new Orient No. 2 mine in southern Illinois where union officials had just negotiated a new scale for loading-machine operators. A strike occurred at once. It wasn't a strike of loading-machine men, but of men running coal cutters. The agreement, which had just been written, provided that these men should receive the union scale of thirteen cents a ton and that until scales were installed at the mine, their method of checking coal should be left to the machine men involved and the management. But when the men could not readily fix with the mine superintendent upon a method of payment, they struck. Naturally the company insisted that they go back to work and then take up the case under the contract. It was simply another instance of unauthorized striking.

A probable reason for this strike is that the men had been working steadily developing the mine for a considerable period in spite of the fact that fishing was pretty good. But such a strike could hardly have occurred, no matter how powerful the lure of the cat-fish, had it not been for the union state of mind. In Illinois, the union's strength these many years has produced a superiority complex in the minds of the men. This attitude is infrequently seen during times like these, but it still is likely to crop out in men who have been eating three square meals a day and who ride back and forth to work in automobiles of their own. They forget that they have pledged themselves to keep the mine running and settle disputes by peaceful methods. They forget that they are pledged, as union men to support the policies their leaders determine. They are spoiled by the very strength of their union.

Now that unionism is in distress everywhere, there is ample reason for President Lewis to campaign the fields he still holds, declaring in no uncertain terms that the very life of the union depends upon union men living up to their contracts. Said he in Iowa: "There devolves upon your union the same degree of obligation that exists in the making of a contract between two men. . . . If a man in some business transaction violate his word to you once, twice, thrice, you arrive at a point where you no longer deal with him because of loss of confidence. . . . You members of this organization will understand that when officers of your union ask you to carry out your wage agreements they are doing so to protect your own record as an organization. The existence of the United Mine Workers of America must be justified if it is going to exist."

These are no longer hollow words. They used to pass the union miner by without affecting him emotionally beyond tickling his risibilities slightly. Now they send a shiver down into his stomach. It is an unpleasant shiver. The union miner doesn't thank anybody for stimulating that sensation within him. But he has got to experience it for the good of the industry. It takes a good leader to go about the unionized fields giving it to him without disrupting the union in the process. President Lewis is that kind of a leader. So we rise once more to hope that Mr. Lewis will stick to his job even though the health of President Gompers of the American Federation of Labor is again reported to be frail.

A Stripping Shovel and Car-Haul Incline

## Getting More Work from a Stripping Shovel

Long-Reach Stripping Shovels Are Slow in Operation—  
By Providing a Separate Machine to Waste the Spoil the  
Capacity of a Small Shovel May Be Greatly Increased

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*  
Pittsburgh, Pa.

**M**ACHINE stripping, from its humble beginning fifty years ago, when a cover 15 ft. in thickness was considered a mountain, has been developed to such an extent that uncovering coal 60 ft. below the surface soon will be commonplace. In all this progress importance should be attached to the development of equipment rather than to the actual methods of stripping. It is the equipment and its performance that determine the economical limits of any stripping operation.

The biggest of present-day shovels will uncover coal at depths of as much as 60 ft. below the surface. This may perhaps be done at a profit if the market is favorable, but in all probability some other form of equipment could be used that would reduce the operating cost. There is a practical limit to the size of the shovels that can be used for stripping coal. Increased capacity and reach entail increased weight which tends to crush the coal bench on which the shovel travels. These large shovels also can be manipulated only with a large labor force and at the expenditure of more power. The capacity of a shovel for work is not proportional to the length of its reach, and its efficiency, theoretically, decreases as its size is increased.

Thousands of acres of coal lie under a cover that is only slightly thicker than that which heretofore has been stripped by shovels. Coal thus protected by heavy cover, is more merchantable than that from shallow stripping and should find a ready sale, especially if the bed is advantageously located with respect to its natural market. Under such circumstances the ratio of thickness of cover to thickness of coal which in the

standard practice of the past in the northern coal fields has been fixed at six to one, might be expected to increase if the coal is buried under an overburden not exceeding 60 ft. Purer coal and reduced cost of stripping might be instrumental in making the ratio as high as 10 to 1. Thus the stripping of a 6-ft. bed under 60 ft. of cover might be entirely feasible.

### COMBINATION OF SHOVEL AND BELT FAILED

Back in 1904 George E. Turner built a stripping machine near Missionfield, Ill., incorporating in its construction a long conveyor boom and a short-boom shovel. Both of these devices were mounted on a single truck and functioned and operated as a unit. Later on the shovel attachment was removed from the conveyor truck and its place taken by an independent steam shovel. Two units were thus provided which acted independently of each other. As recounted by Grant Holmes in an article entitled "Early Coal Stripping Full of Heartbreak," published in the June 5 issue of *Coal Age*, the conveyor machine was "a theoretical success but a practical failure." The belt had to be replaced frequently and various other parts constantly were breaking. This experiment apparently blasted the hopes of stripping men so far as the belt conveyor for carrying heterogeneous materials, such as a mixture of clay, shale and slate, from the pit to the spoil bank, was concerned. Consequently up to the present few attempts have been made to apply conveyor belts to the disposition of stripped material.

In 1915 the Dobbie Foundry & Machinery Co., of Niagara Falls, New York, built a portable incline to handle two solid-body cars or skips which are filled with spoil by a small stripping shovel. Each skip is then drawn separately by a hoist and rope to the top of the incline, where it enters a dump and is tipped

NOTE—Naturally a small shovel can work faster than a big one. By employing an incline to dispose of the spoil as shown in the headpiece the shovel can be kept steadily at work digging overburden. Each machine thus does only the work for which it was designed and together they can dig and waste as much overburden as could a far larger shovel alone.

forward on its front wheels, discharging its contents onto the spoil bank below. The purpose of the Dobbie portable incline and the Turner conveyor are identical, both serving to carry the overburden from a small stripping shovel to a waste bank. The construction of the Dobbie portable incline, however, is quite unlike that of the Turner machine and overcomes the objectionable features that were responsible for the failure of the latter.

As shown in the accompanying illustrations the frame of this incline is in reality a cantilever truss made up of I-beams, angles, channels and plates which is tied to a bedframe of H-beams. This bedframe rests on four railroad trucks set in pairs on a wide double track to prevent rocking. The incline on a slope of 18 deg. is 173 ft. long over all and has a rise of 64 ft. from the top of the track rail to the tip of the truss. The dump is so located as to permit the building of a spoil pile 52 ft. high, with its vertex 150 ft. horizontally from the bucket of the stripping shovel. The long overhang of structural steel which projects toward

into the dump, the front wheels remain on the track while the auxiliary wheels on the rear axle follow the elevating rails, swinging the car into an almost vertical position about the front axle as an axis. These details are shown clearly in Fig. 3.

The Dobbie portable incline has been used successfully for nine years at the limestone quarry of the Diamond Portland Cement Co., Middle Branch, Ohio, in conjunction with a steam shovel for stripping overburden preparatory to quarrying operations. The limestone formation worked at this quarry is the Putnam Hill bed. It attains a thickness of 8 to 10 ft., is underlaid by the No. 4 coal seam and covered by sandy loam, clay and slate. The average thickness of the overburden is 15 ft., the maximum being about 36 ft. Where the thickness of the cover is greater than 20 ft., shale occurs directly above the limestone. Otherwise the cover is all of a loose sandy nature.

Because the thickness of the overburden is fairly uniform, it is stripped off by parallel cuts extending across the property. The berm, or exposed bench of

FIG. 1  
Wasting Spoil

This view of the portable incline is taken from the spoil bank. It shows the simple construction of the cantilever with the car or skip dump at its upper extremity. This machine is capable of wasting as much spoil as could be dug and wasted by a giant stripping shovel. A comparatively small steam shovel in combination with this incline are thus able to do as much work as a big expensive stripper. The view which is naturally foreshortened shows the incline out of proportion. The headpiece gives a better idea of the relative sizes.

and above the waste pile is counterweighted by a reinforced-concrete block cast on the bedframe of the incline.

On this incline two tracks are laid. Each consists of 60-lb. rails on an 84-in. track gage. On each track runs a 5-cu.yd. solid-body car which is pulled up and lowered down the incline by a 1½-in. steel rope, guided by sheaves and securely attached to the car.

Each car is raised and lowered independently by its own cylindrical hoist drum. These two drums are driven in tandem through a train of gears by a 100-hp. 440-volt induction motor, which also is geared to a small slow-motion drum for propelling the incline. The entire machine is moved by a snatch block and cable.

In the dump section of the incline the car track proper is horizontal. On each side of it at the dumping point, however, are placed elevating rails which engage a pair of wheels on the rear axle of the car outside of the regular track wheels. As the rope pulls the car

limestone, between the stripping and loading shovels is about 85 ft. wide. Approximately 60 ft. of this width is occupied by the carriage and short overhang of the incline, the remaining 25 ft. representing the width of cut made by the stripping shovel. The rock or quarrying shovel, which follows the stripper at a distance of 400 to 500 ft., naturally, handles a cut of limestone no wider than the stripping cut. On reaching the end of a cut, the stripper "runs back light" to the point of starting, each successive cut being made in the same direction.

Several reasons that justify "running back light" and making all cuts in one direction might be given. Chief of these, however, is the necessity for keeping the stripping and loading shovels some distance apart in order to maintain a reserve of exposed limestone in front of the loading shovel. This intervening distance between shovels must be maintained also in order to keep the incline out of the blasting zone. The difficulty encountered in maneuvering the incline—that is, in

Fig. 2—Loading a Car on the Incline

Solid-body cars are used on this incline. Each car holds about two dippers full of spoil and makes one trip to every four dips of the shovel.

turning it—demands that it be “moved back light.” If the incline were mounted on caterpillars, it would be more portable and obviously the necessity for “moving back light” would be removed.

The stripping shovel, is an old machine having a swing of only 180 deg. It is operated by steam and has a  $2\frac{1}{2}$ -cu.yd. dipper. Being of the railroad type, much time is lost in moving up after each “bite,” as well as in striking the bank several times in order to fill the dipper. Much of this time could be saved through the use of a caterpillar-mounted shovel.

Inasmuch as the quarry practically adjoins the company's cement plant an alternating-current transmission line is carried to the strip pit. As was stated earlier in this article, the incline is electrically driven. So is also the rock shovel which has a  $1\frac{1}{2}$ -cu.yd. dipper. The incoming alternating current of 440 volts is converted to direct current of 220 volts by a motor-generator set mounted directly on the shovel. A portable compressor unit which supplies air for drilling blast holes is also electrically driven.

The  $2\frac{1}{2}$ -cu.yd. stripping shovel and the portable incline have about the same capacity when working with fairly heavy cover. This outfit has successfully stripped overburden as thick as 36 ft. Although the shovel boom is not long enough to reach the top of a bank of this height, it successfully handles heavy overburden by undermining and caving. It is believed that the incline is capable of handling cover 40 ft. thick. Larger inclines of course could be built to handle still heavier covers. Where shale occurs it is usually blasted.

Fig. 3—Car Tilted Into Dumping Position

The dumping arrangements are extremely simple. The front wheels of the car follow a level track while the auxiliary wheels on the rear axle rise upon auxiliary inclined rails. By this means the car is up-ended to practically a vertical position.

When working in cover 35 ft. thick, this incline has handled 2,900 cu.yd. of shale and loose sandy material in 10 hr. Under extremely favorable conditions, it has transported to the dump as much as 185 cu.yd. in 13 min.

The number of men required to operate and move the stripping shovel and the incline depends upon the thickness of the cover being stripped. When working in light cover the labor charge per ton of material handled is comparatively high because the equipment must be moved up frequently. Where the cover is about 20 ft. thick eleven men comprise the stripping crew. Three of these operate the shovel, one attends the incline while the remaining seven lay track and perform the other duties incident to moving the shovel and incline.

This company is preparing to open a new limestone quarry not far from the nearly-depleted one now being worked. It has made a thorough examination of the property. Test holes show that the average thickness of the cover is about 20 ft., and that the overburden consists almost entirely of loose, sandy material. It is the intention, therefore, to strip with an electric shovel which will deposit the spoil material on a portable incline conveyor.

#### RUBBER CONVEYOR BELT WILL SUPPLANT SKIPS

On this latter piece of equipment a 2-ft. rubber belt will be utilized in place of cars for carrying the spoil to the top of the incline. The shovel will deposit the

Fig. 4—Looking Down Incline Toward Shovel

There is nothing complicated about this equipment. The cables attached to the cars are led around sheaves at the top of the truss and thence beneath it to the tandem drums of the electric hoist.

stripped material in a small bin which will be covered by a grizzly to keep out large pieces that are liable to choke the throat of the bin. A steel-pan conveyor feeder will regulate the flow of spoil material from the bin to the rubber belt which will be housed in a gallery. The belt will be driven by a 20-hp. and the incline propelled by a 50-hp. motor. Both shovel and incline will be mounted on caterpillar trucks.

Though the reach of the cantilever truss on the conveyor incline will be equal to that of the car incline now in use, it need not be so heavy. The live load on the car incline is about 20,000 lb., and exerts its greatest force during the dumping of the car at the end of the cantilever. The overhang of the truss, on both car and conveyor inclines is about 100 ft. A 2-ft. belt will carry about 25 lb. of load per linear foot or a total of 2,500 lb. The conveyor also eliminates the stresses which are set up by the impact in dumping a car.

It is believed that the conveyor incline mounted on caterpillars, together with a  $1\frac{1}{2}$ -cu.yd. full-revolving

Fig. 5—Moving the Incline Forward

In order to keep the incline alongside the shovel it must be moved up periodically. This is done by means of a cable that is wound onto a small drum on the car hoist. A dead man or multiple-stake anchor forms an ample fastening for the snatch block.

electric shovel, similarly mounted, will handle as much material as the largest type of shovel now in general use. The stripping shovel will have a radius of 33 ft. at an elevation of 8 ft. Not only is this lighter equipment expected to handle as much material as a giant shovel, but it can be operated with one-third the labor or perhaps even less. It is reasonably certain that four men will be able to perform all the duties incident to the operation and movement of both the shovel and the conveyor incline.

In the stripping of coal the Dobbie incline should

find many applications. Experience gained in several industries in handling a mixture consisting of exceedingly small-, and large-sized pieces precludes the utilization of rubber-belt conveyors. If the rubber-belt or steel-pan cannot be made to work satisfactorily reliance must be placed on a car-haul arrangement on an incline, the success of which has been convincingly demonstrated by nine years of service in the Middle Branch limestone quarry. In any event, the incline and also the shovels will probably work to best advantage when mounted on caterpillars. It seems likely that coal strippers have neglected a feasible piece of equipment that advantageously might be employed in stripping coal under cover ranging from 20 to 60 ft. in thickness.

Possibly the Dobbie portable incline, with a 100-ft. cantilever truss and 5-cu.yd. cars, working in conjunction with a small stripping shovel, might not handle as much material per shift as a machine with a 90-ft. boom and a 6-cu.yd. dipper; nevertheless, in the final analysis the combination of two small machines has several merits to recommend its use. The investment in a portable electric incline and a small electric shovel, both mounted on caterpillar trucks, is less than half that necessary for an electric shovel of a size sufficient to do the same work as the former equipment. It is believed by some that shovels weighing as much as 300 tons some day will be mounted successfully on caterpillars. Thus, far, however, this feat has not been accomplished, and until it is the comparatively light portable incline mounted on caterpillars, can be moved readily along the berm, thereby eliminating much lost time and considerable labor.

## The Miner's Torch

### On Regulating King Coal

"OLD King Coal, was a jolly old soul!"  
Perhaps he was but he isn't now.

Everyone is agreed that he has no soul and furthermore he needs a super-king or something of the sort to make him behave. The only reason that he has not already been put under surveillance is that no two people can agree as to just how a super-king should act, in fact I rather think if the truth were known that they don't exactly know what a super-king is.

First, Congress as a body tried to visualize the Super-King myth; that got the President interested. The President appointed a Commission and they got interested. The Commission formulated a voluminous report which they gave out in installments and each installment interested an editor or two; by the time all of the installments reach the daylight of publicity all of the editors in the country will probably have become interested. Now, to make matters worse, some of our Congressmen have decided that their first guess was wrong so they are beginning all over again, armed with the information and suggestions brought out by the President's Commission and the newspaper editors who commented on the Commission's report.

It will take at least another year before all of the editors and the politicians who have become interested will have had a chance to talk and write themselves out;

and in the meantime what will happen, in fact, has already happened? Only this:—One can buy all of the coal that one wants at a fair price and the quality is satisfactory. When this information becomes generally known the editors and the politicians will lose interest in King Coal and his dominions.

So far as I can discover no one is entitled to credit for bringing about these improved conditions in the coal industry. They are simply and wholly the result of circumstances beyond the control of kings and super-kings, to say nothing of politicians.

The miner who loaded dirty coal has had a change of heart because he knows that there are plenty of men ready to take his place if he is discharged. The operator who has been loading washer refuse and calling it coal has gone out of business because mines producing coal with a reputation as to quality are only running three and four days a week. The broker who made a practice of watching the coal cars in the railroad yards so that he might boost prices whenever a shortage was in prospect has given up in disgust and changed his line of endeavor. And as for price of coal, it is, of course, higher than it was in pre-war days but it is so near to the actual mine cost that only the best equipped mines are now being operated on a profitable basis. Even the United Mine Workers have seen the light and have postponed indefinitely the next strike.

So long as the erstwhile King Coal is a pauper and furnishes all the coal the public wants he will be forgotten, but as soon as the market changes and Coal is once more King the public will dig up its wise saws about the eternal need that the producers of essentials serve the public at minimum profit and in adequate quantity without recoupment of losses.

# Should Mines Be Subjected to a Yearly Valuation?

As the Probable Life of a Mine Changes with Development, as Market Requirements and Conditions Modify Profits and as Such Changes Demand Operating and Financial Reconstructions, Frequent Revaluations Are Desirable

BY C. P. MCCORMACK

Consulting Mining Engineer, Crowell & Murray, Cleveland, Ohio

**C**OAL, metal or non-metallic mines—it makes no difference—all are hazardous and swayed by the same gods of chance. Good business demands that all the knowledge and control possible be applied to the gamble that underlies such operations.

Whether operations were initiated under a fully detailed layout carried to the point of exhaustion or just a vague development scheme, upsetting agents are liable to enter year by year. Thus a continual investigation and readjustment is necessary to assure of an ultimate profitable conclusion. An annual survey of the entire mine is the check that will determine if ultimate success is assured.

All mines need a revaluation—a research to ascertain if their discounted worth is what it was at their last inventory less the extracted profits to date. This valuation, each time, should consider the mine as a new property, using the past operation as a guide.

Such a survey is a forecast of succeeding operations. Then, if the previous planning does not fit in with this forecast of the final result it should be altered. Changes in the occurrence of mineral, changes in methods, equipment, labor, geological controls, grades of product, markets and economics are some of the factors that influence the new forecast and scrap those made in the past. On the other hand the operations should not be revised unadvisedly as a well-engineered initial plan will terminate more successfully if not tampered with or subjected to continual alteration. But an investigation of the mine in its entirety is the only way to check up these plans or the governing factors. This applies even more forcibly to enterprises the managements of which at starting did not attempt to construct a definite program.

Mines with a production of 3,000 tons per day and upward, whether run singly or in groups, are as vulnerable to these conditions as the little 200-tonner. In fact, more so, as their far-flung workings are more liable to run out of bounds than the easily overseen small operation. The large corporations with technical staffs employ them chiefly on the going production as this department is seldom overmanned. And in addition these technicians are often blocked by historic methods and the "practical man." But without a comprehensive look into the future that same great smooth running plant ultimately may tangle itself into a Gordian knot.

Small mines with only the fatherly hand of the operating man, intent on costs and the myriad daily details to direct its destiny are in dire need of this valuation. With no compensating operation to tide it over, many a constricted mine had much better shut up shop now if the future is all guesswork. Whether the company is large or small and has, or fails to have, its own experts, an outsider's viewpoint is likely to be enlightening as prejudice in favor of their past plans may warp the judgment of the company's engineers. The future may be held only too readily to fit into the past.

Few other industries fail to have periodical analyses made of their resources, producing conditions and prospects. Accountants are called in, inventories are taken, markets are investigated, adjustments are made for the trend of the times and the future is planned anew. Yet these businesses have known reserves and have a growing life. All the more reason then why a mine with its wasting assets should try in every way to safeguard its limited existence and apply all the certainties possible to its hazards.

A mine valuation may have many forms and be carried into wondrous detail according to the proclivities of the examining engineer and the demands of the client. But boiled down, a report should show the ultimate earnings and the present worth derived from a discounting of these profits.

To discover the ultimate earnings, the following main facts should be ascertained: (1) Reserves to date segregated into known, probable and possible tonnages, (2) sampling and grade of tonnage, (3) condition of the mine and plant, (4) possible yearly production, (5) costs, values and expected profits, deduced from operating plans and life and taken over a certain average period.

The present worth, which is the indicator and final figure for comparison, is derived as follows: (1) Operating plans based on reserves, grade and condition of the mine are devised or revamped or approved; (2) life of mine is ascertained from operating plans and in consideration of markets and desired financial return; (3) ultimate earnings are discounted over the derived life and based on desired financial returns, which give the amortization and the return on the investment, and thus determine the present worth. This is the climax of the story telling how profitable the operation

---

**E**ACH MINE when opened should have some definite plan, not alone as to its engineering but also as to its financial future. On its projected life depend its present worth and the expenditures that may be profitably made in its development. As the mine is operated a clearer idea is obtained as to its mineral resources, as to the percentage of mineral that can be extracted, as to cost of production and the market price of the product. Many changes occur that make a revision of former estimates necessary. Are these revisions made? Mr. McCormack says they are not. In his belief they should be made yearly.

---

really is and how it compares with past ideas or what could be earned in other industries with same investment and risks.

The examining engineer in his field work accumulates the data on the reserves, grade and condition, paying due consideration to exploration, development and geological factors and to adjoining operations and history of the district. The balance of the items are gained from a study of the field data. All or a portion of this information may or may not have been obtained on the mining property before it was developed. If never procured no operation of the property should have been considered. If once possessed and never rechecked, then the enterprise is sailing on an uncharted sea with only a lucky star for a compass.

As has been said before, a valuation is a forecast

and as no forecast can be absolute—as it is humanly impossible to look into untouched formations or foretell exactly the economics of years hence—then the more often a forecast is made the closer it approaches the truth. In a thirty-year life how much more accurate is the forecast made in the fifteenth or seventeenth year of what will happen on the twenty-seventh year than is the valuation of the fourth

year. It is certain that any capital asked to invest in a mining operation will demand the value on the date of that request and no other. Therefore as the operator's money is of the same worth as the capitalist's, it is equally befitting that he know to the same degree just where his property stands.

Even in the short interval of a year many changes may occur to crystallize the future for the property. Taking the main features of the report, as itemized above, into consideration the following are some of the influences constantly at work which will affect the welfare and profoundly modify the ultimate end of the venture:

(1) Knowledge of the deposit newly acquired from work at adjoining operations, from the development of the district or from the developments of the mine itself may change tonnages from probable into possible or may raise or lower the total reserves. As these are the primary assets of the company, any change in their totals is of vital importance. Simply deducting each year's production from an original estimate is by far too inexact a method in view of the yearly depletion of the known resources leaving the less definitely developed reserves as the sole resource of the future.

(2) Original geological inferences now may be so incorrect as to reapportion the probable and possible tonnages. As all mines at birth are regarded optimistically with reference to these estimated blocks, their alterations become serious.

(3) Explorations and developments recently completed should call for a revaluation because, whether they verify the original calculations or disprove them, a new basis for evaluation is created.

(4) Resampling may alter the expected grades and, in conjunction with new treatments, markets and eco-

nomics of the industry, this changing of grades or consequent value is tremendously important. It is emphasized here that, if the mineral is closely and expertly sampled continuously and the information is kept plotted on analyses maps, the present and future condition of the mine will be judged with a greater degree of certainty.

(5) Pushing of one part of the initially planned harmonious operation ahead of another may breed difficulty later on. This calls for prompt rectification despite the fact that apparently the work may be progressing smoothly.

(6) Gouging of low-cost tonnage or "high-grading" may have skimmed the cream needed later on. The down-grade returns after the peak of the life are thus aggravated, and now is the time to ascertain if the

candle is burning at both ends.

(7) The plant may be found to be too small for coming yearly production based on new market or reserve conditions. Hence a fresh investment is demanded, and a valuation shows what change in present worth this would occasion.

(8) Or the plant may be found to be so oversized that production should be speeded up to utilize its

capacity economically, thus shortening the life and putting a new value on the discounted earnings.

(9) If the workings are so spread out that co-ordinated supervision has become difficult, the condition of the mine may have become so involved—yet unheeded—that larger losses ultimately will be sustained and the earnings will be decreased.

(10) New equipment or methods may now be successfully installed, with consideration of other factors, that will give better results. Or they may be thought ready to install when in reality the final conclusion does not justify them. Only a survey gathering all the parts together can prove this.

(11) Labor demands or man productivity are constantly changing and calling for other means to accomplish the desired results than those once thought adequate. How best obtained can only be ascertained from a detailed investigation as labor is the major consideration in every phase of the operation.

(12) Redetermined values and costs may differ so radically from those of the last valuation that the new figures will be astounding. The fair average period basis of one or two years ago may now be seen to be wholly wrong. As costs are fully as important as values, and more fluctuating, the expected earnings hinge on this more than on any other of the factors.

(13) Operating plans may be found to be incapable of producing the required tonnage and thus require alteration. A comprehensive survey will show whether other plans will be justified at higher cost but larger tonnage; or just what the ultimate cost of the new plans will be. If not warranted, then the life must be lengthened and the present worth decreased for the same reserves.

(14) Appreciable requisitioned expenditures are only

---

**N**O CAPITALIST would invest money on the basis of an estimate of the value of a property made many years ago. He would want to know the value at the date of investment. Can the owner or owners of a property satisfy himself or themselves by trusting to a survey or a plan made many years ago when less was known as to the mineral resources, the capacity of the plant, the character of the market and a number of other factors, the character of which is more clearly revealed by the passage of time?

---

justified by a proven increase in the ultimate earnings. An expenditure of \$100,000 on a plant or a new shaft may show a decrease in costs over a certain tonnage but it is guesswork to justify it unless there is enough surely proven tonnage that the profits will absorb the investment. Even then the proof may not be conclusive as co-ordinate operations are vital factors. Therefore a valuation of the entire operation is the only absolute guarantee that the expenditure is justified.

(15) Due to far-reaching influences and financial conditions, capital may now require other returns than it formerly did and only complete revaluation can be depended upon to devise the proper means.

It is clear that any one of the above factors or a combination of few or all are likely to be found in any mining enterprise and to be fundamentally important in determining the ultimate profits. As there is always the strong possibility that one or more of these agents will be working in various directions—sometimes unknown, sometimes unheeded—an annual valuation is a necessity. And mines have controlling peculiarities: one will be in danger of excessive costs though its reserves will furnish a safe and stable background; another's health depends on its preparation charges; the price of product raises or decreases the value of a mine which otherwise would be a world beater. In these cases too much interest may be centered on the governing trait, and a yearly valuation is needed to keep the rest of the house in order.

The following example will illustrate how even two or three of these forces, quietly acting, affect the functioning of a mine and how the survey explores and corrects to the best possible degree these conditions:

A certain mine was being worked on room-and-pillar panel system on two adjacent, steeply pitching troughing seams outcropping at surface. The main haulage-ways were being extended on the strike in 300-ft. lifts. The original exploration had been made by drilling from surface and from the outcrop and the original estimates had been based on this exploration and on the bed as already developed. The mine was opened in 1914, was put into full producing shape in 1917 and had been operated to date. Costs and prices have been assumed for purpose of illustration.

The total reserves were 10,000,000 tons which at 90 per cent recovery gave a recoverable reserve of 9,000,000 tons. The maximum production being averaged at 500,000 tons annually a plant to assure that capacity was constructed. Accordingly the property was estimated to have an eighteen year life.

Product given average value of \$6.50 per ton.....	} Average basing period 1907-1917	\$2,500,000
Product given average cost of \$5.75 per ton.....		
Net profits accordingly estimated at \$0.75 per ton.....		
Capitalization.....		

The annual net profit was figured at \$375,000 equaling 15 per cent dividend on capitalization. The amortization and capital return was figured at 4 and 10 per cent respectively, which for an eighteen year life would require a 14 per cent dividend. Thus estimated the dividend more than meets all requirements.

The total expected profits of \$6,750,000 when discounted to present worth at 4 and 10 per cent for an eighteen year life equals \$2,700,000.

During the operations of the last year, the workings up the pitch encountered numerous pinched-out areas and one end of the operation was cut off by a fault. Increased labor-and-material costs and demands of the market for closer and cleaner sizing drove costs up to \$6.25, values meanwhile rising only to \$6.85, thus leaving a net profit of \$0.60 per ton. An off-market had only absorbed 400,000 tons, leaving the schedule 100,000 tons behind. From the recoverable reserves of 9,000,000 tons had been extracted 2,400,000 tons; therefore the future reserves were thought to be 6,500,000, allowing 100,000 tons for local pinches. The remaining life of the property was estimated to be at least 13 years.

This would give the present worth of expected profit from date (still holding to original 75c. per ton profit as it was thought that the basis would return to normal) to be \$2,330,000.

Due to uneasiness on part of some of the principal stockholders, a valuation report was made which disclosed the following facts: Pinched-out areas and data on faults from this and surrounding properties

proved that seams were cut off from outcrops and displaced and that the total recoverable reserves were now only 5,500,000 tons at a 90 per cent recovery, but it was estimated that if the present operations were continued the recovery would drop to 85 per cent due to mining losses along the pinched areas and the fault. Thus the recoverable reserves would be only 5,200,000 tons. The plant was not large enough to handle more than 500,000 tons annually, therefore off-year set backs could not be made up later. These off years should be expected to occur on the average about every sixth year. The costs and prices now obtained were shown to be more nearly normal for the life of mine as the old basis would never return. This gave only a 10-year life at an output of 500,000 tons annually and an annual profit of only \$300,000 which was a 12 per cent dividend on the \$2,500,000 capitalization, whereas 19½ per cent was now required. The present worth of total expected profits was now only \$1,636,500, as compared with \$2,330,000 before.

The report showed that by certain changes in mining methods, the recovery could be raised to 93 per cent (if installed at once) giving recoverable reserves of 5,650,000 tons. By changes in plant costing \$100,000 the straight annual production could be raised to 650,000 tons with reserve capacity of 100,000 tons to make up for off years. This would cut costs to \$6.10 including depreciation on the new \$100,000 investment, thus leaving a margin of \$0.75 per ton profit or a net annual profit of \$487,500. This would be a 19½ per cent dividend on the capitalization, whereas 17 per cent would be required. The present worth of expected profits was now \$2,100,000 after allowing for interest on the \$100,000 additional plant.

Now, as the present worth of all expected profits determines the intrinsic value of a mine, a comparison

of the above various stages will show how a revaluation proved the condition and bettered it.

	Recoverable Reserves	Annual Required Per Cent	Dividend Obtained Per Cent	Present Worth
As thought to be before the valuation.....	6,500,000	14	15	\$2,330,000
As the valuation proved it to be..	5,200,000	19½	12	1,636,500
As the valuation showed it could be.....	5,650,000	17	19½	2,100,000

Much of the above discussion may be "old stuff" and proverbial to the majority of operators, but it is as true today as when first stated and yet how often are these facts overlooked. As long as the mine is safe, reserves stretch out ahead and the hoist is overtaxed now, why bother with a valuation! The insurance companies and public health boards are advocating annual physi-

cal examinations as the surest means of staving off disease. But how many men going briskly about their business have an inherent fear of voluntarily learning the truth about themselves. The theory of letting well enough alone in both men and mines is not sound business.

The engineer has a greater place in the mining industry other than in examining prospects, laying out plans and reporting for seller or buyer of properties. If he is given the periodical opportunity to pry into and lay bare the conditions of the vital organs of the mine, then proper functioning by them is assured and a full life more certain. He should be the Chinese doctor who is paid to keep his patients agoing as well as the diagnostician and physician for those stricken with maladies.

### Storage-Battery Locomotives Increase Safety in the Mines

FOR years the coal mines of the country have been seeking an ever increasing degree of safety. While the greatest danger to life and limb within the mines is unquestionably the "fall of roof or coal," nevertheless other dangers are always present, some of which may be guarded against far more effectively than can the fall.

Among these latter perils is the explosion of gas or dust—disasters which in the twinkling of an eye snuff out dozens, perhaps scores of lives. Prevention is beyond doubt the best cure for these evils. If ignition is rendered impossible propagation throughout the mine is likewise out of the question. As a palliative, however, rendering it impossible for a simple gas ignition to develop into a violent explosion, rock dusting of mine workings is being largely practiced. Nevertheless the safest mines will be those wherein all known means of preventing accidents are employed.

The accompanying illustration shows two locomotives recently installed by the Phelps Dodge Corporation in its No. 6 mine near Dawson, N. M., the photograph being furnished by W. D. Holman of that company. These machines are of the storage-battery and combination storage-battery-and-trolley type. Each is fitted with an 88-cell, 29-plate lead battery having a capacity of 480 amp. hr. The combination machine operates

when outside the mine on a trolley voltage of 260. It is provided with an automatic charging device and safety interlock. Both machines are flash-proof in every detail.

Each of these units weighs 19½ tons. They may be used either singly or coupled together. When employed in this latter way they form an articulated unit weighing 39 tons which is probably the heaviest machine of its kind used in American coal mining. Each time this unit comes to the surface the battery charge is "boosted" or "sweetened" by current from the trolley.

Of course coal mining will always be dangerous, just as is farming, railroading, fishing and many another calling. The danger involved, however, will be in approximately an inverse ratio to the precautions taken to avoid accident. While carelessness on the part of employees probably never can be entirely overcome the other factors that enter into almost every mine accident can be largely controlled. Thus while it may be impossible, for instance, to prevent men from carrying matches into the mines and surreptitiously indulging in an occasional smoke, it is entirely possible to so treat the mine with inert stone dust as to render the propagation of an explosion, which may be initiated by such carelessness or bravado out of the question. The use of flash-proof storage-battery locomotives in place of those of trolley type will do away with one of the sources of gas ignition which in the past has been a somewhat fruitful source of mine accident.

#### A Heavy Unit

These locomotives, which weigh nearly 20 tons each, may be used either independently or coupled together. When employed in this latter manner they form an articulated unit probably larger than any other used in American coal mines. The battery charge is boosted every time the machine comes to the surface and operates on the trolley.

# To Prevent Fouling, Swivel Mine-Car Hitchings Should Be Lubricated

By J. W. POWELL  
Contracting Engineer  
Welch, W. Va.

THE most important requisite of a swivel hitching is that it shall always function easily with no tendency to foul while a trip of cars is being dumped. In fact, the successful operation of a rotary dump depends in large measure upon the proper swiveling of the hitchings. I recall the experience of a large coal company that installed a rotary dump and equipped its cars with swivel hitchings, only to discover too late that they fouled so frequently that the cars had to be uncoupled before being dumped. Thus, one of the most important advantages of this type of dump was wholly lost.

Other important features of a good swivel hitching are that it should have maximum strength without excessive weight, a minimum of wear and friction, and that it should resist rust and corrosion, especially between the swivel head and its seat.

The swivel hitchings described in this article have been designed to assure these results and provide a coupling that will always function with a minimum of wear and friction, and no corrosion of the swivel head or seat as a result of the action of acids. This makes the hitching practically indestructible.

Referring to the drawings, it will be seen that the most salient feature of this hitching is the means provided for automatic lubrication of the swivel head and seat, the points of greatest wear. The swivel head in every case is completely inclosed in a metal chamber that can be packed with grease or other lubricant. This grease slowly works its way out of this container through the clearance space provided for the swivel shank, but in so doing, it thoroughly lubricates the swivel head and seat. This prevents the destructive

action of rust and acids on the metal and reduces the friction and wear to a minimum. The metal chamber protects the swivel head from injury. Its spherical shape gives maximum strength and resistance to shock, distortion and crushing.

Type A hitching is adapted to round-bumpered cars. It consists, as shown, of a hollow spherical steel casting provided with an eye to receive a link. It has one cored hole for the assembly plug and one for the swivel shank. In assembling, the link is installed in the usual manner by forging it in place after the swivel head has been formed. A thin paste of emery dust and oil or a similar abrasive is then placed in the chamber and the swivel head and seat ground together under tension.

All abrasive is then flushed out with oil after which the assembly plug is babbitted in place. The lubricant chamber is then filled and sealed with a small plug. Grinding can be omitted if desired, allowing the swivel parts to work in and seat themselves in service. In the largest size of this type of hitching, the swivel casting weighs about 7 lb. and the total weight of hitching ranges from 10 to 18 lb. depending on the distance between the coupling pins.

Type B hitching has a double swivel and is likewise adapted to round-bumpered cars. It is assembled in the same manner as Type A, but swivels somewhat more easily because of its double head. The weight of the swivel casting is about 6 lb. for the largest size, and the weight of the entire hitching is from 10 to 16 lb. depending on the distance between coupling pins.

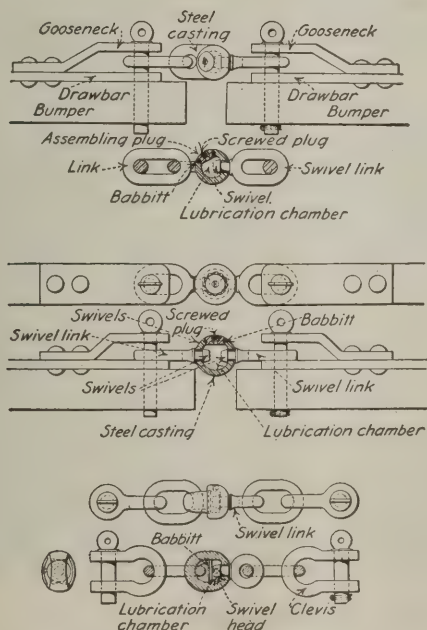

Type C hitching is adapted to square-end or double-bumpered mine cars and replaces the middle link in the plain three-link coupling. Its length has been reduced to about that of a plain link, so that the complete hitching is as flexible as that composed of three ordinary links. This has been accomplished without any sacrifice in strength or ease of swiveling. It is assembled in the same manner as types A and B. The weight of swivel in this type of hitching is about 5 lb. and the weight of the complete coupling is practically the same as that of a plain three-link hitching of a similar overall length.

The lubricating principle embodied in these hitchings could be applied to almost any type of swivel, and would prevent the rapid wear which is caused by the corrosive acids or fumes found in mines. Application has been made for patent rights. In cost and weight the couplings described will compare favorably with types embodying a swivel.

## Test Zinc Chloride as Wood Preserver

Director E. R. Weidlein of Mellon Institute of Industrial Research of the University of Pittsburgh has announced the founding of an Industrial Fellowship on the treatment of timber. This research, which is being sustained by the Grasselli Chemical Co., of Cleveland, Ohio, and is conducted by Dr. A. M. Howald, will seek the best methods of applying zinc chloride to the preservation of wood.

Investigational work which was begun during 1923 will be continued throughout the present year. An experimental wood-impregnating plant is maintained for practical tests of processes. Under the supervision of Dr. Howald means are being sought of increasing the permanence of zinc-chloride treatments of timber by the addition of petroleum oils.

### To Make Swivel Hitchings Turn

Three types of swivels, the top Type A, the middle Type B and the lower Type C. Type A is for round-bumpered cars and has only a single swivel. Type B has a double swivel and is also for cars with round bumpers. Type C is for square-end or double-bumpered mine cars.

### Outstanding Scenes In and Around the Glen Alden Mines—I

(1) Crusher under the Baker breaker. This, like most of the other crushers in the same breaker, rests firmly on the ground. (2) Automatic telephone in use underground at Truesdale Colliery which saves the attendance needed at a central station and also makes it possible to avoid the delays incident to calling on "central" to make the necessary connections. (3) Fan at Nanticoke boiler-house which ventilates

the interior of the boiler-room in summer. Unventilated boiler-rooms in warm weather have temperatures comparable only to those in a ship's stokehold. (4) Efficiently steel-timbered haulway at Auchincloss Colliery. (5) Loading a car by scraper bucket at Truesdale Colliery. The scraper conveyor has made possible the operation of thin seams which otherwise could not be worked profitably.

### Outstanding Scenes In and Around the Glen Alden Mines—II

(6) Glen Alden's largest lamphouse. This building has 1,000 flame safety lamps and 800 electric cap lamps on its racks. It supplies the Loomis Colliery. (7) Automatic water still for storage-battery supply. (8) Nanticoke pump which is moved up or down according to the stage of the Susquehanna River. (9) Room at Cuyaga shaft, Storrs Colliery, built to accommodate steam pump now occupied by an electric unit.

Note the saving of space. The pump has an automatic control device designed by E. J. Falloon, hydraulic engineer of the Glen Alden. Room is about 25 x 76 ft. (10) New kind of locomotive at No. 17 Slope, Woodward Colliery, which operates on a heavy grade lowering loads and raising empties. It functions by winding in and paying out a cable. (11) Gasoline tractor hauling mine timber at Baber Colliery.

# A Direct-Current Power-Distributing System That Keeps the Mine Equipment Working

Need for Higher Operating Efficiencies Has Created a Demand for Automatic Devices — Troubles in Power Circuit Are Localized so That Serious Delays Cannot Occur

BY RAYMOND HOWEY

Electrical Field Engineer, Lehigh Valley Coal Co.,  
Mount Carmel, Pa.

IN RECENT years the many labor and mining problems have made it almost absolutely imperative for every coal-mining company to turn to the use of electrically operated machinery. As a consequence, with amazing rapidity, a vast system of electric power-distributing lines has grown which must be kept under control and be protected against delays, overloads and many forms of danger. This in turn has presented a problem of providing adequate protection for large and small power-generating and power-using machines.

Much of the old equipment used in and around the mines was originally protected by fuses. As power loads increased, more important, larger and more expensive generators, converting apparatus, transformers, feeder lines and motors were installed. The dangers attending the use of heavier currents and the importance of power delays are now greatly magnified and have made necessary the application of many different forms of protective devices and switches.

Stress of economic problems has made it more and more necessary that every saving of power operation, maintenance and labor be effected. The necessities for continuity of service, for taking advantage of diversities of loads, for intricate feeder systems, for localizing power disturbances and overloads, together with high labor and equipment costs have created a need and demand for automatic control apparatus. Consequently, during the last few years its application has increased steadily. The development of apparatus which performs a given duty more cheaply than manual operation has given great impetus to this movement. But there is another factor which has been more potent. The manufacturers of automatically operated equipment have, in many cases, been able to design apparatus which operates more quickly, more accurately and more reliably than the human brain. Some of these devices act as feelers which detect, locate, measure, sec-

tionalize and almost anticipate overloads, short-circuits and grounds.

Much of the progress which has been made is also due in a large measure to those mine electrical engineers who have spent time and effort to help the manufacturers perfect their apparatus and properly interpret the requirements of the industry. The history of most successful devices, used in mines, therefore, almost invariably includes a long chapter of co-operative effort between the man who uses the apparatus and the manufacturer. By this direct contact the manufacturer gets to know the adverse conditions of the mines and when he has developed his apparatus he can feel sure it is acceptable to the many engineers of the industry.

The success which the Lehigh Valley Coal Co. has had with automatic circuit-breakers and substations recently led it to install at the Centralia Colliery, Centralia, Pa., a carefully devised system for controlling and protecting the direct-current feeders. At this mine there are three substations for converting alternating current to direct current. Each machine is rated at 200 kw. and supplies 275-volt direct-current energy.

These machines are located on the surface at points about a mile apart. At A in Fig. 1 is an automatic synchronous motor-generator outfit, at B and C manually operated synchronous converters are used. All

Fig. 1—Complete Underground Power Distributing System Showing How Continuity of Service Is Made Possible by Use of Automatic Circuit-Controlling Devices

Three sources of direct-current supply are tied together by means of station and tie-feeder type circuit breakers. The main generator breakers are tripped open only under unusual conditions. When overloads occur special relays first relieve the generators of the less important loads so that the main circuits and the more essential mining equipment may operate almost continually. Repair and adjustment of the control devices may be made at any time. Bypass double-throw knife switches disconnect the breakers from the lines but maintain service. By the use of only two different type breakers, maintenance costs are greatly reduced and the workmen quickly learn how to make any necessary adjustments and repairs.

machines receive their alternating-current supply from the same transformer substation but through three different distributing lines running from the main transformer bank. The direct-current output of each machine passes through an automatic reclosing circuit breaker shown at  $A_1$ ,  $B_1$  and  $C_1$ . These breakers each have a normal rating of 800 amp. and are known as booster station panels.

Before installing automatic breakers inside the mines the chief problem was to eliminate delays caused by interruption of power on the main feeders running from the various substations. High peak loads, short circuits and grounds were almost continually opening the main breakers in the substations. These delays were also caused by trouble with the wiring of some of the mine equipment, by falls of rock bringing the trolley or feeder into contact with the rails, by steel cars jumping off the track and touching the trolley, by overzealous locomotive operators starting trips of cars too quickly.

As a result of these difficulties the substation equipment was being overloaded almost continuously, throwing the whole generating capacity of the machines off the lines an average of forty times during an eight-hour day. Delays lasted from ten seconds to five or fifteen minutes depending upon the cause. Often the delays were much longer, especially when a short-circuit had to be located by the workmen and sectionalized by hand-operated switches. As automatic reclosing circuit breakers have been installed in the mines, as will be described, the main booster station breakers now open an average of once a day and that is usually only when the converting equipment is shut down for the night.

#### BREAKERS DO NOT TRY TO RECLOSE ON OVERLOAD

These booster station breakers operate as follows:

- (1) Are closed by an electro-magnet, provided the generator voltage is of correct value and other conditions are normal.
- (2) Open automatically in case of overload from any cause, voltage failure or reverse current.
- (3) Remain open a definite time interval, regardless of cause for opening.
- (4) At expiration of this time interval, reclose automatically provided the generator voltage is of correct value, correct polarity, and provided there is no short-circuit or overload condition on the load side.

These breakers make no attempt to reclose while the overload conditions exist, but reclose instantly upon removal of the conditions which cause or would result in overloads. A diagram of these breakers is shown in Fig. 2.

Each breaker is set to open when 1,450 amp. are flowing and reclose in eight seconds, provided the voltage at the center of the bridging resistance is about 250 volts. Depending upon conditions, the breaker can be made to reclose when a slight load remains on the circuit. This is to obviate the necessity for cutting off the dead load of lamp circuits and small motors which ordinarily stay connected to the lines when the breaker opens.

For inspection and repair purposes the breakers may be completely disconnected from the lines by means of a two-pole, single-throw 800-amp. enclosed knife switch mounted directly below on the same pipe-frame support as the breaker. One pole of the switch disconnects the main feeder from the breaker while the other opens

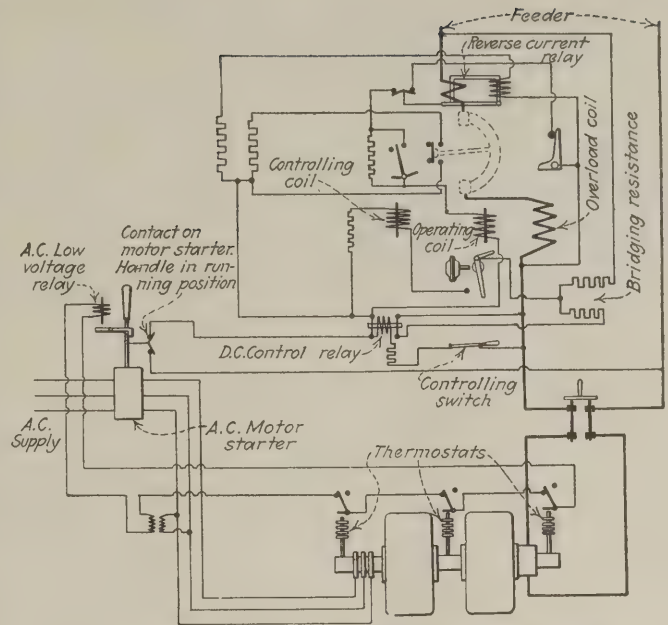

Fig. 2—Control Circuit of Booster-Station Panels

These breakers completely protect the generating machines and main feeders. Auxiliary equipment connected to the breaker makes the operation of the direct-current side of power-converting machines and direct-connected generators automatic.

the circuit from the machine; thus when the switch is opened the device is entirely de-energized.

At points  $a_2$ ,  $a_3$ ,  $a_4$ ,  $b_2$ ,  $b_3$ ,  $b_4$ ,  $c_2$ ,  $c_3$ , and  $c_4$ , in Fig. 1, the current passes through 600-amp., 275-volt, tie-feeder type automatic reclosing circuit breakers, located inside the mines. This type of breaker is generally used in circuits supplied with energy from the different sources. It opens on overload, irrespective of the direction in which the current may be going at the time.

Its operating characteristics are as follows: (1) Breaker is closed by means of an electro-magnet. (2) Opens automatically in case of overload on either side, or voltage failure. (3) Remains open a definite time interval regardless of cause of opening. (4) At the expiration of time interval, if there is a short-circuit or overload on either side of the controller, it makes no attempt to reclose while the overload condition exists, but closes instantly upon removal of short circuit or overload condition. A wiring diagram of this breaker is shown in Fig. 3.

These breakers are disconnected for inspection or repairs by a two-pole 600-amp. double-throw enclosed safety switch. When the switch blades are in the upper position the breaker is in service. When the switch blades are thrown to lower position power is bypassed around the breaker. Inspection or repairs can then be made with perfect safety to those making them while power is still being supplied to the circuit to which the breaker was connected.

The output of machine  $C$  goes through a 1,000,000-c.m. cable down a shaft a distance of 350 ft. where it divides into two section feeders. Breaker  $c_2$  is set to open at 800 amp. and  $c_3$  is set for 600 amp., consequently the total overload settings of these two feeder-circuit controllers equals 1,400 amp. or 50 amp. less than the overload setting of the main breaker at  $c_1$ . It is obvious that the only time the main breaker will open on overload is when there is a current of 1,450 amp. passing through it, which can only be caused by a short-circuit on the main feeder between the machine and breakers  $c_2$  and  $c_3$ , upon failure of one of the

breakers or when either one or both are cut out of service for inspection or repairs as described above.

The advantage of this method of connection readily will be seen, because when the controllers are in service the only section that will be cut off from a supply of power will be the one having the overload or short circuit on it.

The output of machine *A* is limited in exactly the same manner as machine *C*; the output of machine *B* is also limited by similar means with the exception that power from *B* first passes through two 600-amp. instantaneous overload relays, connected as illustrated at *OR*<sub>1</sub> and *OR*<sub>2</sub> in Fig. 1. These relays are set to operate at 600 and 800 amp. respectively.

When the combined load on breakers *a*<sub>1</sub> and *b*<sub>2</sub> becomes excessive relay *OR*<sub>1</sub> opens breaker *a*<sub>1</sub>. This often prevents the main breaker, *B*<sub>1</sub>, from opening and shutting down all the equipment close to it. Similarly relay *OR*<sub>2</sub> first opens breaker *b*<sub>2</sub> to relieve its load and later opens breaker *b*<sub>1</sub> if the overload condition or relay *OR*<sub>2</sub> persists.

#### HAVE LOCATED RELAYS NEAR CONTROLLERS

Each relay is located near the controller or controllers it is desired to disconnect, the controller being disconnected when the relay operates on the overload current for which it is set. Normally closed contacts on the *OR* relays open the control circuit of the tie-feeder breakers.

The use of these relays means a saving of the pur-

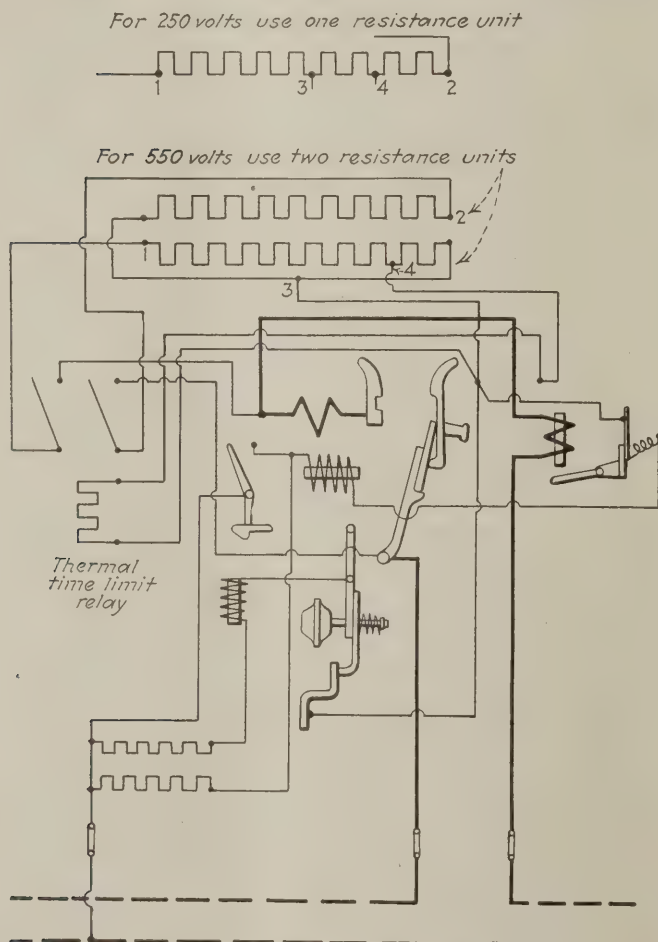

Fig. 3—Tie-Feeder Circuit Controller

Like the booster station breaker this device provides protection much better than that which could be accomplished by manual operation. It opens regardless of the direction of the current through the overload coil. Just as soon as the overload condition is removed it automatically recloses and re-establishes service.

chase and maintenance of two additional automatic breakers and in turn also simplifies the system. This arrangement may appear complicated but it really is not. It provides continuity of service by the use of the minimum number of control units.

Machines *A*, *B* and *C* are tied together by means of a 500,000-c.m. feeder cable which runs along main haulageways inside the mines. Breakers *a*<sub>3</sub>, *a*<sub>4</sub>, *c*<sub>1</sub> and *c*<sub>2</sub> sectionalize any overloads which may occur along this line and any disturbance is localized within its particular section.

#### BREAKERS ARE OF TIE-FEEDER TYPE

Breakers *a*<sub>2</sub>, *b*<sub>2</sub>, *b*<sub>3</sub>, *b*<sub>4</sub> and *c*<sub>3</sub>, although used for independent feeder service, are of the tie-feeder type and therefore are available to replace one of the more important tie-feeder controllers should the occasion arise. By using tie-feeder breakers throughout it is always safe to interconnect different sections should future mining development necessitate changes or an additional substation at the end of one or more of the independent feeder circuits.

With this arrangement there are only two different types of breakers to be familiar with, carry spare parts for and maintain. As the load shifts from one section to another it makes it possible to maintain a fairly balanced feeder system and to obtain the many advantages of power saving, continuity of service, etc. already enumerated.

#### Builds Two-Ton Mine Car in Five Hours

JOSEPH MARTIN, car repairman at Whipple, W. Va., for the New River Co., on June 11 assembled a mine car complete, including greasing, in five hours and eight minutes. And this is just a sample of his everyday work. The car has an average capacity of 3,800 lb. All the boards were sawed by Mr. Martin without assistance with the exception of the timbers used in the bottom. As this could not be done by one man, a blacksmith assisted him in cutting them. To bind the car together Mr. Martin bored 148 holes, inserted bolts and screwed on the necessary nuts making them tight. Mr. Martin has often built a car in the same approximate time. Of course, the irons of the car were shaped and drilled ready for assembling or building of the car, whichever is the more correct term.

#### May Feed Immunized Coal Dust to Hogs

The Department of Agriculture, says *The Explosives Engineer*, declares that a dust mixture of about 60 to 75 per cent limestone and 25 to 40 per cent coal is a good base from which to build a desirable food for swine, so we can feed the immunized floor dust in the mine to the hogs when we wish to replenish it with fresh limestone dust.

Dr. Davis, of the Bureau of Fisheries, welcomes rock dust, believing it will greatly reduce the acidity of mine drainage water and help to prevent the destruction of fish after a mine has been thoroughly and repeatedly dusted for many years. This will reduce the pressure for restrictive legislation. Departing from the authority first above mentioned it may be added that the presence of limestone may reduce pump and pipe corrosion and so may help to justify stone dusting as an economic measure altogether apart from its preventive value with regard to mine explosions.

# News Of the Industry

## World Conference at London Surveys Power Resources

**All Authorities but New Zealanders and Some Canadians Favor Private Ownership—Non-Friable Coke Made by Low-Temperature Process—Hydrogenation Solution of Benzol Problem**

After preparations of more than a year the World's Power Conference met at London, June 30 to July 12, with representatives of some thirty-eight countries present. As O. C. Merrill so well stated at the opening session, "Technology, economics and finance know neither politics nor parties and recognize no boundaries of race, nationality, language or creed." International comity is being established, men of different nationalities are becoming acquainted in the closest manner and the engineer is doing yeoman service in knitting a war-weary world.

The British did not fail to stage the conference well. The Prince of Wales, honorary president of the congress, addressed the opening session, and the Earl of Derby, the president of the conference, conducted the session. Sir Joseph Cook spoke for the British dominions, saying that today the world needs a balancing of accounts rather than a balance of power, which could be attained only by developing power to the fullest extent and by seeking to obtain it from new sources.

M. Guillaume, Director of Mines for France, and Guido Semenza, of Italy, replied for France and the other countries of Europe respectively. Dr. Kamo spoke for Japan and other Asiatic countries. O. C. Merrill, secretary of the Federal Power Commission of the United States, replied for the United States and South American countries, making a speech that was among the best at the conference.

### Papers Cover World's Power

The scientific papers were delivered in the conference halls of the British Empire Exhibition, Wembley, London. In a few sessions the papers were read by title only; at others they were read at some length, hindering discussion. They covered the power resources of the world, the economic-financial, legal and government policies in regard to power, power development, water-progress, steam-power plants and equipment and the preparation of fuels. Fifty-five papers were presented relative to power resources.

J. P. Noonan, president of the organized electrical workers of the United States, representing the American Federation of Labor, stated that labor stands unequivocally ready to

co-operate to the fullest extent in the development of power. The present labor movement, said Mr. Noonan, realizes that labor-saving machinery is really for labor's benefit. He urged a closer contact and a better understanding between labor and employer. Lack of understanding, said he, has caused both sides to be suspicious of each other and has caused labor to spend money and time in an endeavor to defeat

---

World power conferences by introducing the developments of one country to the representatives of another will speed up the world's progress. Even the big advances travel but slowly from country to country. The smaller devices and less showy methods lie still longer untransported. Travel has been left largely to the idlers of the world. It is well that today the aggressive engineers are meeting in world congresses, the better guaranteeing that the world hereafter will dwell in peace.

---

legislation which when later examined proved to be for the good of labor and not for its detriment.

Government ownership naturally had few adherents. Even in Italy the government has tired of railroad operation and would part with its railroads if it could find anyone who would buy and operate them. The Canadians connected with the hydro-electric power development of course defended government ownership, and the New Zealanders declared that only by such means could power have been distributed to the most distant farmhouse of their country, but they were little disposed to recommend their practice to others.

Dr. Arthur T. Hadley, president emeritus of Yale University, said that experience had shown that an industry not completely developed and standardized—and few, it may be added, are of this character—could not be handled satisfactorily by the govern-

ment. Sir Philip Lloyd Graeme, of Great Britain, declared that the function of the government with regard to power development was to make laws that would attract capital to development, and that at times of stress it may go further and use its credit and even its cash to make possible developments that otherwise would be retarded. Dr. George Otis Smith, director of the U. S. Geological Survey, advocated "public regulation always; government operation never."

### Discusses Steam Power Plants

Two interesting sessions dealt with steam-power plants. Pulverized coal and boiler construction were the leading subjects. One session was devoted to turbines. Four papers were presented on illumination.

Three sessions were devoted to preparation of fuels. Prof. H. E. Armstrong exhibited Coalite manufactured from Kent coal and showed that it was far from friable. He said that it was made from finely powdered coal by carbonization in iron retorts at a temperature of 600 deg. and in about four hours. The yield of coke was about 80 per cent, but the yield of oil was low. Dr. R. Lessing declared that we can hope to convert the whole of the coal substance into liquid only by hydrogenation. He said that we could not expect to get the needed supplies of oils from coal except by some such process and that Dr. Franz Fischer's paper gave only a limited promise of success.

### Sufficient Oil from Coal Unlikely

The presence of oxygenated compounds in coal made it unlikely that we would ever get such large quantities of oil from coal as we desired. The oil described by Dr. Fischer was not made by the Bergius process but synthetically from carbon monoxide and hydrogen by polymerization. Dr. C. H. Lander said that some fifteen or twenty different ways of distilling coal at low temperatures had been tried, some of which the government had financed. Some had resulted in making good coke, good oil and sufficient gas, but the experiments had been unsuccessful because the plants had depreciated so rapidly or because the initial and maintenance costs were so heavy that they could not be a financial success.

Mr. Orrock, United States, said that the gas works could do little in the way of low-temperature carbonization so long as the load factors were only 30 to 35 per cent. The process was advantageous only where the load factors reached 40 to 50 per cent. Higher factors than these were found

nowhere except at a few metallurgical works running 24 hours a day and seven days a week. Byproduct recovery could be applied readily to a power station, but it was extremely expensive and many plants that had been started as byproduct plants ultimately restricted themselves to the making of gas and coke only, as the market for sulphate of ammonia and for tar was altogether too uncertain. The manufacture of oil from coal would not be profitable till the price rose considerably.

B. F. Haanel, of Canada, said that the central Canadians had accustomed themselves to the use of anthracite, and their stoves were adapted for the burning of that fuel. Consequently the Canadian Fuel Board was endeavoring to find a Canadian product that would be a good substitute for United States anthracite. It was making investigations into the possibilities of erecting coke-oven plants at strategic points where the Nova Scotia coals could be coked into a domestic fuel that would substitute for anthracite and produce gas for domestic and industrial purposes.

#### Canada's Problem in Lignites

Hydrogenation of coals seemed to him a far cry, for the natural oils would not be exhausted for years. The problem for Canada was the use of low-grade lignites which were not suitable in the raw state for steam or domestic purposes. Important especially was the question as to what could be done with it for railroad purposes. Though experiments had been proceeding with Saskatchewan and Manitoba lignites for five years no commercial success had been attained. It appeared that the logical way to deal with lignite was to pulverize it. A central heating plant was being installed in Winnipeg at which these lignites would be pulverized and used for the generation of steam.

A. E. Douglass, the Fuller-Lehigh Co., Fullerton, Pa., said that the average cost of pulverizing at twenty-six of the most recent plants in America was 45c. per ton, where 100 tons were used per day. This figure embraced everything except fixed charges. It covered labor, repairs, power and lubrication, cost of cleaning buildings and supervision. Where the consumption was 150 tons a day the cost was 41c. a ton; with a consumption of 200 tons per day the cost fell to 40c.; with 250 tons to 38c.; with 400 tons to 36c.; with 500 tons to 34c., whereas for plants using over 1,000 tons per day the coal could be pulverized for slightly under 32c. per ton. These figures were averaged for anthracite, lignite and bituminous coals. With anthracite the cost was higher than with bituminous, probably owing to cost of repairs and increased power for pulverizing.

Mr. Douglass said that in most cases where proper storage bins had been installed the pulverized coal had given no trouble. The temperature should not exceed 200 deg. F., and the moisture content should not be too high. To show how powdered fuel can be stored, Mr. Douglass instanced a case in Seat-

#### Wheat Crop to Help Coal Business in Southwest

One of the handicaps of the coal business during the past year in the great agricultural belt of the Midwest was the farmer's inability to pay his bills because of low prices for his crops. This year the prospect is brighter, according to a bulletin of the Colorado & New Mexico Coal Operators' Association just issued by its secretary, F. O. Sandstrom, of Denver. Wheat, which sold well under \$1 last year, is now trading in Chicago, Kansas City, St. Louis and Minneapolis at around \$1.30 and the Southwest is about to harvest a bumper crop.

Mr. Sandstrom's figures show that the combined yield of Kansas, Nebraska, Oklahoma, Texas and Colorado was 177,288,000 bushels last year and will be approximately 241,000,000 bushels this year, making a net increase of 63,000,000 bushels, or about 35 per cent. The carriers serving that territory, he finds, are well equipped to move the crop, as indicated by ample supplies of cars in uniformly good condition. "This," writes Mr. Sandstrom, "should naturally be reflected in an increased coal tonnage to this consuming territory."

tle where pulverized coal had been stored for seven months, from the hot season to the fall. He did not advocate the manufacture and use of pulverized coal at small industrial plants where good quality coal was at hand. As a matter of fact he was turning down several hundred inquiries a year from small industrial plants.

Mr. Douglass said that in Australia pulverized fuel is being made from brown lignite having 22 to 28 per cent of moisture. It is used in locomotives.

In western Canada coals having 18 per cent of moisture and 30 per cent of ash were being pulverized for fuel, and he added that where similar coals were being used in sugar-refining plants in British Columbia an efficiency of 83 per cent has been obtained. Similar fuels had been pulverized and were being used for railway purposes in Italy, Holland, Brazil and Manchuria.

#### Powdered Coal Highly Efficient

David Brownlie, discussing the papers on fuel economy, said that with pulverized fuel an efficiency of 90 to 92 per cent, and with mechanical stokers of 88 per cent, could be attained, but the methods of testing were so varied that the recorded efficiency might vary 3 per cent. There were three methods of testing boilers, those of the American Society of Mechanical Engineers, the Continental Code of the German Society of Engineers and the British Code of the Institution of Civil Engineers. This last, Mr. Brownlie declared, was a disgrace to British technicians.

#### Ten Men Die in Second Gas Explosion at Gates Mine

Ten miners were killed on July 25 at 7:30 p.m. by a gas explosion of unknown origin in the Gates shaft mine of the H. C. Frick Coke Co., at Gates, Fayette County, Pa. It is said that 120 men on the night shift were in the mine, but as the explosion was local in nature all but the ten men who were killed reached the outside safely and little property damage resulted. In February of 1922 an explosion ignited by a blown-out shot in this mine killed 25 men.

Whether the explosion originated at the face of an entry or in a room has not been determined definitely, nor is the agent of ignition known. It is not likely that a blown-out shot ignited the gas, as shooting had not yet begun when the explosion took place. In view of the fact that electric cap lamps are worn exclusively by the workers and electric drills were not in use, it is possible that a defective cutting machine was the agent of ignition. The Gates mine has been working every day.

The H. C. Frick Coke Co. is so well equipped and otherwise prepared for mine-rescue work that it did not require the aid of the U. S. Bureau of Mines rescue car and crew located at Pittsburgh. Gas analyses taken soon after the explosion showed that the oxygen content of the air in all parts of the mine was sufficient to support life, for which reason gas masks were worn extensively by the rescue crews. All the bodies of the victims were recovered soon after the explosion.

The explosion, according to Coroner Baltz, was discovered in a most unusual manner. John Kelly, a Gates miner, was returning to Gates from Palmer, three miles away, when he noticed a peculiar settlement of dust on his shirt. Kelly stopped to investigate and found that it was coal dust.

Knowing that the dust from a mine very rarely reaches the surface, he glanced toward the mouth of the Palmer mine and saw a cloud of smoke and dust floating from the shaft mouth.

Kelly ran to the Palmer foreman's office and sounded the alarm. Ten rescue crews donned helmets and, believing that the Palmer workings were on fire, they went into that mine.

Their search was fruitless. Kelly recalled that an old tunnel connected the Palmer and Gates mines and he suggested that the trouble was in the latter working. Within a few minutes the rescuers were on their way to the Gates pit. As they reached the shaft they met a crew of miners coming out.

These miners, at work two miles from the scene of the explosion, knew nothing of the blast. But the rescuers went down and soon found the cave-in, behind which ten bodies were located.

S. Pemberton Hutchinson, president of the National Coal Association, will return from his European trip Aug. 15. While in Europe Mr. Hutchinson has been making some general observations as to the possibilities of increasing the exports of American coal.

## Stocks Nearly Worked Off, Better Demand and More Work Soon, Says Brophy

Altoona, Pa., July 30.—“Much of the surplus stock of coal has been worked off, and we have every reason to believe that within the next few weeks there will be some improvement in demand and more work at the mines,” said John Brophy, president of District No. 2, United Mine Workers, at union headquarters in Clearfield, when asked by *Coal Age* to make a statement regarding the immediate outlook for the coal industry in his district.

Many of the operators in the district are non-committal as to possible developments in the early autumn while several agree with President Brophy and have not hesitated to predict at least a partial resumption of mining following a long period of inactivity.

It was pointed out that some of the collieries are now making preparations which would indicate that they expect to operate on a more extensive scale at an early date. It also was ascertained that some of the leading operators are anything but hopeful.

The spring and summer of 1924 have been the dulllest in the history of the district, and not only have the miners and their families felt the depression but every industry directly or indirectly affected has suffered. Merchants report heavily decreased sales and hundreds of young miners have departed from the mining centers and found employment in other lines of industry, thus lessening the purchasing forces of the coal communities.

Extreme pessimism has prevailed, especially in those communities which depend wholly or largely on the coal trade.

### Many Mines Closed Down

From operator sources regarded as authoritative it was ascertained that of the 191 mines on the Tyrone and Clearfield branch of the Pennsylvania R.R. and its feeders, 141 mines are now closed down entirely. Thirty-five of the remaining 50 are operating on an average of five days a week and 15 only two days a week.

At Morrisdale, normally a good coal town, there was mine work one day during the week ended July 19. No. 1 shaft and No. 2 shaft of the Morrisdale Coal Co. are closed down entirely and there is little or nothing doing at the Cunard Coal Co.'s slope.

Operators are quite generally of the opinion that a lower wage scale, which would enable them to produce at a lower cost, would partly solve the problem, a contention that is not admitted by President Brophy, nor is it admitted by many well-informed miners of the district. But the operators' view is fairly well expressed in the answer given by one of the leading producers in the Philipsburg region when asked to diagnose the situation.

“There is nothing the matter with the coal business,” said he, “except that there isn't any and no prospects of getting any. There can be no coal business to amount to anything in the Clearfield region as long as the costs of production are in excess of those in competitive regions. The union wage

James L. Cooney

Recently chosen president of the Scranton Coal Co. in succession to the late Frank E. Platt. He was general manager just previous to his accession to the presidency.

scale does not permit the operator to dispose of the product of his mine at prices which the operators in the non-union fields quote. The buyers of fuel purchase at the lowest quoted prices, other things being equal.”

The manager of one of the leading coal corporations operating in the central Pennsylvania field, speaking of conditions and prospects, said:

“Operators of long experience know that April generally is the low production month of the year. Operators were, therefore, of the opinion that the low output last April was characteristic of past performance, and they expected that business would improve during each succeeding summer month. This hope was badly shattered when the month of May showed no improvement over April and when June production was lower than May. The indications are that July will be worse than either, both as to price and production.”

Of the operators disposed to take a more cheerful view of the near future in mining is James Wilson, brother of William B. Wilson, Secretary of Labor in the late President Wilson's Cabinet. He is associated with the Conestoga Coal Co., in Irvona, and the Acme Coal Co., of Philipsburg, two organizations that might quite properly be classed among the big body of smaller operations whose combined output shows up large in production totals. Mr. Wilson takes the stand that the extreme dullness in the coal trade is nearly certain to be followed by a movement in the opposite direction. The cooler weather, he states, will bring a demand for coal.

One of the disquieting developments of the situation is the growing impression that the operators are engaged in a freeze-out game. One hears of it frequently in conversing with miners. Like views have been expressed by persons not engaged in the mining industry in any capacity. It is charged that the operators after entering into an agreement with the union miners have apparently made no effort to obtain orders or run the mines, but are themselves quietly but none the less effec-

tively on strike. Such a view, however, is not held by Mr. Brophy, who maintains overdevelopment is the chief reason for the depression. His statement, in full, follows:

“The coal trade is unusually dull in this district. That is admitted. But we do not agree to the claim of many of the operators that this district alone is affected by slack work. All bituminous districts, union and non-union, are alike affected, as shown by the report of the Geological Survey for the week ending June 28, which gives the percentage of full time output for central Pennsylvania at 41.1; Maryland, which is operated non-union, 39.1 per cent, while the New River field of West Virginia, also non-union, which is so often referred to by the operators of this district as an active competitor, 48.5 per cent.

“Overdevelopment is the reason for bituminous coal being a part-time industry. With double the mine development necessary to take care of the market needs of the country, slack work is chronic. This condition has been intensified by some slowing down in business during the last twelve months, and the further fact that large surplus stocks of coal were accumulated during last winter and the three first months of this year in anticipation of a possible strike.

### Much of Surplus Worked Off

“When the strike did not materialize, the stocks of coal had to be worked off before the users would buy, even in quantities equal to current consumption. Much of the surplus stock has been worked off by this time, and we have every reason to believe that within the next few weeks there will be some improvement in demand and more work at the mines.

“Lowering the union scale would not benefit the coal trade any, because the non-union operators could and would promptly reduce wages so as to maintain a lower rate than the union rate. Each union reduction would be followed by a non-union reduction. The demand for coal would be unchanged and the miners would have no more work and would be reduced to abject poverty.

“The mine worker is entitled to a decent livelihood. The consumers are entitled to ample fuel at reasonable prices. If the present managers, the operators, cannot bring the industry to a basis of efficiency that will assure these two things, the operators must expect the people ultimately to demand legislation that will regulate the coal industry.”

Northern Cambria County is in practically the same straits as the Clearfield and Philipsburg region. The Pennsylvania R.R. has discontinued hauling coal over the Bellwood division and all coal must get to the main line by way of Cresson. In the Johnstown district there is a little more activity due to the Bethlehem Steel operations and railroad contracts at South Fork and other points along the main line.

Somerset County is shipping most of the coal from the district by reason of a lower or non-union scale. Business in Indiana and other counties in the district continues in the dull class.

C. W. Bryan's Municipal Coal Yard

As Mayor of Lincoln, Neb., Charles W. Bryan, now Governor of Nebraska and nominee for Vice-President on the Democratic ticket, established a municipal coal yard to protect the public against "coal barons." The gentleman in the foreground is E. H. Shroder, a real estate operator and friend of Mr. Bryan, who lent his co-operation to make the plant possible.

### Consumer Can Remedy Coal Troubles by Initiative in Storage, Says Hammond

In heavier storage lies largely the solution of the difficulties of the coal industry, according to the foreword which John Hays Hammond prepared for the report of the Coal Storage Committee of the American Engineering Council. The consumer, Mr. Hammond thinks, should take the initiative in bringing about a remedy.

"This report on an engineering survey of the possibilities of improving the method of procuring and storing coal should appeal to producers, carriers and consumers as the key to the solution of many of their troubles," says Mr. Hammond, who was chairman of the U. S. Coal Commission.

"The President's Coal Commission, learning of the purpose of the American Engineering Council to make such a study, assigned to it the task of conducting an extended engineering survey of the storage of coal. The commission and other government departments have collaborated with the American Engineering Council extensively, the survey has been conducted by over 400 engineers in leading industrial centers, and the report has been formulated by a committee of prominent engineers recognized authorities in each branch of the subject covered.

"The operation of the coal industry probably is beset with more difficulty than any other of the great American industries, due to prevailing intermittence of operation. If this evil could be removed it is plainly evident that a tremendous step would be taken in regularizing the coal industry and in helping other industries which are partially or wholly dependent on coal.

"The solution undoubtedly lies in greater storage. A reasonable accumu-

lation in storage will permit of more even production throughout the year, deflation of the coal industry, continuous employment of labor, relief of congestion on railroads during their maximum demand season, removal of the coal 'feast or famine' conditions among consumers and many other allied troubles that are now felt as coal takes its course from mine to point of combustion.

"The fears of loss by the consumer have been studied by the committee and largely dispelled.

"In the past the operators have said that storage is the duty of the railroads, whereas the carriers have contended that it is the duty of the consumer, and as a result storing has been neglected. This cycle must be broken, and a unified, economically sound practice established. The report wisely recommends and urges that the consumer, potentially the largest benefactor, should apply the needed balance wheel through himself initiating storage."

### Strike at Loader Mine In Illinois Continues

The strike of cutting-machine runners in Orient No. 2 mine of the Chicago, Wilmington & Franklin Coal Co. runs its steady course without a sign of break. This is the mine in which the first Illinois machine loader scale of \$10.07 a day was agreed to by men and company and which took effect July 16. The mining-machine men struck on that day, asking 14.6c. a ton instead of the 13c. agreed to in the new contract, and objected to the system of territory assignments besides registering other kicks at the new order of things in the mine. The men who operate mechanical loaders were ready to work under the contract but the cutting-machine operators have tied up the property.

### Wages of Hard-Coal Miners Rise Faster Than Those of Any Other Basic Industry

The average hourly earnings of all groups of wage earners in anthracite mining are now at the highest point since June, 1914, according to an investigation made by the National Industrial Conference Board, New York City. The renewal of the two-year agreement between the miners and the operators, providing for a 10 per cent wage increase, the board states, shows that the increase in average hourly earnings is 190 per cent above the rate of June, 1914. The composite figure of average hourly earnings in the industry covering all groups of wage earners, that is, common, semi-skilled and skilled labor, both inside and out, as well as contract miners, increased from 27.8c. in June, 1914, to 80.7c. in December, 1923. That the wage contract is closely adhered to by the various operators is shown by the fact that since December, 1923, further figures denote practically no change in the average earnings up to May, 1924, the general trend remaining at as steady a level as it did under the old contract.

The highest percentage of increase took place in the case of common outside labor, 218 per cent. The next highest recorded was for semi-skilled inside labor, 207 per cent, closely followed by common inside labor, 205 per cent. Semi-skilled outside labor increased 188 per cent. The lowest per cent of increase for both inside and outside labor was noted for skilled work, being 181 and 170 respectively. The percentage of increase of contract miners was 188.

At the present time the board's index figures reveal that anthracite mining wages have risen to a higher peak since 1914 than those of any other basic industry.

### Drum Deposed as President Of District No. 16

F. J. Drum, president of district 16, United Mine Workers, whose office is at Cumberland, Md., has been requested to resign his office effective July 25, according to James E. Jones, national union organizer, who is temporarily in charge of the district's affairs. No official reason for Drum's dismissal was given.

Drum, who has been president of the district more than ten years, led a mine strike which lasted over twenty months, and finally was given up by the national organization on Nov. 22, 1923. This strike was said to have cost the United Mine Workers over \$750,000 and to have caused the disruption of the union in the George's Creek and upper Potomac fields.

Jones will be assisted in the administration of the district's affairs by William P. Murray, of Pittsburgh, brother of Phil Murray, vice-president of the United Mine Workers' national organization.

District 16 embraces mining regions in Maryland, Pennsylvania and West Virginia.

## Adoption of Illinois Loader Scale Hailed In Washington as Progressive Step

Government Officials Foresee Spread of Machine Mining with Marked Cut in Production Costs—Far-Reaching Effects on Market Expected—Pickup in Union Fields Likely

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Illinois' loader scale came as an unexpected but highly gratifying surprise to official Washington. It is regarded as a progressive step of outstanding importance. Opposition to the employment of machinery in coal mines long has been regarded as one of the sinister things which could be laid at the door of the union. The Illinois membership of the United Mine Workers has been regarded as the most reactionary element in that organization. That it should be willing to take this progressive step is regarded as making certain the universal application of this policy.

On the assumption that this agreement soon will apply to the entire Illinois field, it is predicted that there will be an appreciable lengthening of the radius which marks the limit of the territory in which Illinois coals can compete. This step toward lowering production costs in Illinois did not come too soon, as the mines in that state have been operating at 25 per cent of capacity for four months.

### Markets May Be Affected

It is recognized that this action in Illinois, in conjunction with the acceptance of what is practically equivalent to a reduction in the deadwork scale by the miners in southern Ohio and with the informal understandings at individual mines, will have far-reaching effects on the market situation. The fact that the union fields suddenly find themselves in a position to reduce production costs just at the time when everybody believes the market is turning definitely upward, means that the union fields are going to supply more of the country's requirements for the coming winter than anyone had anticipated.

The southern Ohio agreement is of particular significance to the coal mines of that region, since production for five months has not exceeded 10 per cent of capacity.

### Union Reverses Position

One of the most notorious ways in which labor influence was used to limit output was in the Illinois agreement, where a special clause provided that only fourteen loaders could follow a cutting machine. The fact that the union apparently has reversed its position with regard to machines is expected to increase the amount of machine-mined coal in Indiana and Illinois, particularly, to the point where those states will have as large a percentage of machine-mined coal as West Virginia and Kentucky. No figures for machine-mined coal later than those for 1922 are available, but in that year 67 per cent of the Illinois output was machine-mined as compared with 79 per cent in Kentucky. In 1922, 50 per cent of the Indiana production was machine-mined, whereas 77 per cent of the West Vir-

ginia output was produced in that manner. It is known that the West Virginia and Kentucky output of coal mined by machine is now somewhat higher, but a rapid narrowing of the difference is expected under the new conditions.

### Battle Grows Hotter Against Northwest Rate Boost

The battle to prevent the rate increase Sept. 10 on Illinois and Indiana coal going into the Northwest grows hotter daily. All sorts of petitions to the Interstate Commerce Commission to reopen the lake-dock case have been filed. And now comes the Illinois Commerce Commission with a resolution July 24 asking the state Attorney General to take such action, "by injunction or otherwise," as he may think necessary. The state commission takes an interest because it believes the 28c. increase on Illinois coal into the Twin Cities will cut seriously into Illinois business, thus directly affecting the prosperity of the state's mining industry and the people in it. The depression in Illinois is keen enough already.

The whole course of the adjustment of rates to the Northwest has been tempestuous. The case was bitterly contested in long hearings before the Interstate Commerce Commission more than a year ago. When the decision was finally made in June, leaving rates from the Lake Superior docks to the Twin Cities unchanged and increasing the rail rates from the southward, practically everybody was displeased, even the Northwest dock operators, who had hoped for a reduction in their own haul as well as a larger increase in the Illinois, Indiana and Kentucky haul.

The effective date originally was set for Aug. 21. The carriers protested that there was not time to rearrange and publish the new tariffs within the time limit, which ended July 21, the customary 30 days before the effective date. So they asked for an extension of 30 days. This was refused. Then they asked that the date of publication be set only 10 days before Aug. 21.

Before any decision was made on this a new complication set in. Some of the originating lines, notably the Chicago & Eastern Illinois, which is mainly dependent on coal for its revenue and therefore foresaw a great decrease in business when the coal traffic to the Northwest was reduced, found a loophole. It pointed out that the commission in the decision had directed only the specific respondent lines in the case to increase rates. Since the C. & E. I. was not one of those lines, it announced that it would not increase rates on Northwest coal which it originated.

This caused great confusion among

### Bacon and Beans!

The United Mine Workers' attempt to stem the tide now flowing toward non-unionism in western Kentucky included a recent tour of the field by President John L. Lewis. He addressed some hungry crowds down there, for there has been no work in union mines in that territory for months and there is little prospect of any. However, Mr. Lewis tried to instill courage into the wavering ranks by offering them the stone of prospective victory when they really want bread. Said he at Central City on July 18: "I wish I was as sure of going to heaven as I am of winning this strike." An old woman piped up: "Well, if you-all got any hopes of gittin' into heaven yo' bettah supply mo' bacon 'n' beans."

the other roads until the commission sent that line a telegram couched in pregnant phrases, reminding it that even though it was not specifically mentioned, it was making a bed of thorns for itself if it did not publish rates identical with the other roads. The C. & E. I. gave up.

Then came the commission's order deferring the effective date of the new rates from Aug. 21 to Sept. 10. This helped the railroads some in the matter of time for publishing.

But all this time various protests against the new rates and petitions for a reopening of the whole case were filed by various traffic and shippers' associations throughout the Northwest. The Illinois coal operators filed a long one shooting the commission's order as full of technical holes as possible and suggesting new evidence that of itself would justify a rehearing. The pressure brought upon the commission from all these sources was heavy before the Illinois Commerce Commission adopted its resolution July 24. The state commission enters the case probably with more weight than that exerted by all of the petitioners, because they are directly prejudiced, while it is speaking officially for the whole people of the state.

It is not freely predicted in Illinois what action, if any, may be expected from the Interstate Commerce Commission as a result of all of this, but there is definite hope among coal producers that the commission will not make it necessary for the rates to be dragged into court for a decision. That course, however, might be preceded by an injunction which would maintain the present fabric of tariffs for the whole length of a battle through the courts.

Of course there is no assurance that the Illinois Attorney General will ask an injunction or do anything else. Edward J. Brundage, who holds that office, was operated on for appendicitis last week and probably will take no part in this or any other official action for a few weeks. What his assistants may do is entirely problematical. But the state Commerce Commission has shot its bolt with the adoption of its resolution, and there the matter rests.

## Lewis Probe Averts General Strike at Glen Alden Mines

The recent investigation of numerous strikes among local unions in the anthracite region made by the special committee commissioned by John L. Lewis, International president of the United Mine Workers, is credited with preventing a general strike of the 22,000 employees of the Glen Alden Coal Co., which was called off by general consent July 19 after a meeting of the general grievance committee.

As a result of the meeting all of the Glen Alden workers, including 1,800 employed at the Woodward colliery, who had been on strike for a week, were back at work on July 22. The threat of a general strike came about because of the action of the district officials in revoking the charter of the Woodward local for violation of both the district and international constitutions of the miners' union in calling a strike without the authorization of the district officials.

## Restrains Companies in Use Of Term "Mount Olive"

The Interstate Fuel Co. and the White Ash Coal Co., both of St. Louis, Mo., are ordered by the Federal Trade Commission to cease and desist from making use, by advertisements or otherwise, of the words "Mount Olive" alone or in combination with other words in connection with the sale or offering for sale of coal in commerce, unless the coal so designated is produced at mines located at Mount Olive, Ill., or within a small district contiguous thereto, including Staunton, Ill.

In its investigation of the case the commission found that the respondent companies marketed coal mined in districts other than what is known to the coal trade and to others as the Mount Olive district. Such coal was termed by the respondents as "Guaranteed Mount Olive Coal" and "Coal, Mount Olive Grade."

The findings state that for more than forty years the Mount Olive coal district has produced a coal which has become known to the trade and a substantial part of the consuming public as "Mount Olive Coal." This coal has been extensively advertised under the title "Mount Olive Coal," and has become favorably known because of its high quality and has a higher market value than the coal sold by the respondent companies.

## Southern Ry. to Build Cut-Off

The Interstate Commerce Commission July 17 issued a supplemental order authorizing the Southern Ry. to construct a cut-off outside the city limits of Knoxville, Tenn., about four miles northeast of the location originally planned. This line, as now proposed, will extend from a junction with the Southern's Bristol-Chattanooga line at Caswell to Beverly. About four miles from the latter point connection will be made with the Southern's line extending from Coster yard to Middlesboro, Ky. The new extension will be completed within a year.

## Illinois Town to Hold Mass Meeting Over Coal

Just exactly how black is the future for Illinois coal? The town of Herrin and the county of Williamson, Illinois, want to know. The whole community, in the southern Illinois coal field, is so worked up over the matter that it is to hold a public mass meeting Aug. 20. It has invited the coal operators of the state and the state officials of the United Mine Workers to be present prepared to set forth the case from all angles. The whole southern Illinois region is suffering from all the economic ills which general shutdown and unemployment in its main industry naturally would bring upon it. Although the movement is engineered by the Lions Club of Herrin, it is expected that a great turn-out of miners will be present and everybody is going to have a chance to say his say. This is the first mass meeting of its kind in Illinois.

## N.C.A. Committee to Reduce Waste in Use of Soft Coal

With the idea of developing means and methods which will eliminate waste in the burning of bituminous coal, reducing the smoke nuisance and making bituminous coal a more desirable domestic fuel, the National Coal Association has appointed a research committee to go into those problems. The members of the committee have pledged themselves to attack these problems vigorously. They hope to induce builders to pay as much attention to the heating equipment in a home as they do to the plumbing. Even in large buildings, it is known that too little attention frequently is given the problem of heating them most effectively at the lowest cost.

This action of the National Coal Association follows a recommendation emphasized by Harry L. Gandy in his annual report submitted to the Cincinnati convention. He believes the coal operators will be more than repaid by interesting themselves in consumers' problems. In connection with the work the committee will do, the National Coal Association, will issue a printed booklet dealing with the problems of combustion. The research committee is composed of the following members of the association:

J. C. Brydon, (chairman), president, Quemahoning Creek Coal Co., Baltimore, Md.; L. G. Ball, president Dawson Coal Co., Philadelphia, Pa.; Geo. R. Harrington, president, Chicago, Wilmington & Franklin Coal Co., Chicago, Ill.; J. C. Layne, Jr., vice-president, Marrowbone Mining Co., Cincinnati, Ohio; Louis C. Madeira, 3d, assistant to the president, Madeira, Hill & Co., Philadelphia, Pa.; W. A. Marshall, president, W. A. Marshall & Co., New York City.

## Main Island Creek Co. in Big West Virginia Merger

The West Virginia Coal & Coke Co., of Elkins, W. Va., and affiliated companies in Logan County have acquired the holdings of the Main Island Creek Coal Co., one of the largest producers in the southern part of the state. The amalgamation gives the new concern 58 mines, 225,000 acres of land and between 5,000,000 and 6,000,000 tons of coal as an annual output, making the company the largest in West Virginia. About \$25,000,000 is understood to be involved.

The Main Island Creek company was controlled by the Dalton-Kelly interests of Huntington, with 21 mines in Logan County, and the West Virginia Coal & Coke is affiliated with the Hutchinson Coal Co. of Fairmont. C. N. Hutchinson, of Fairmont, president of the latter company, it is understood, will head the new concern.

## Castlegate Mine Opens Safely

Castlegate mine No. 2, owned by the Utah Fuel Co., of Salt Lake City, Utah, and inactive since early last March as the result of an explosion which cost the lives of 171 men, was reopened on July 21. The mine, it is asserted, has been brought to a high standard of safety. It has been completely equipped with electric lights and rock-dusting and electrical shot-firing devices, as required in the recent amendments to the safety code of the State Industrial Commission.

It is stated that no accumulations of gas were found and but a few indications noted. Analysis of air return showed but 0.12 per cent of methane with a volume of 175,000 cu.ft. of methane in 24 hours. Perforated sprays arranged in circular form have been installed at all partings for sprinkling loaded trips. Other provision has been made for sprinkling cars and loading operations are to be thoroughly wet down.

Pending decision as to the type of rock dust to be used, Chief Inspector of Mines B. W. Dyer recommended the use of gypsum. The shooting system is complete and the company will take away all shooting operations from the miners, drilling and firing by company men when all miners are out of the workings. Certain recommendations are made for further steps in the interest of safety, but in practically every case they are of a character that will permit the mine to continue operation while they are being acted upon.

## Strike Cuts Ruhr May Output

Coal production in the Ruhr during May, according to the *Frankfurter Zeitung*, amounted to 1,310,000 tons, as compared with 7,780,000 tons in May, 1923, and 8,970,000 tons in May, 1913.

Production of coke was 570,000 tons as compared with 1,890,000 in May of last year and 1,920,000 tons in May, 1913. The decline in last May's output was due to the strike.

## Problems In Underground Management

### Few Superintendents Know What Risks Are Run with Explosives

If They Did They Would Increase Supervision, Thus Preventing  
Accidents and Getting a Higher Percentage  
of Lump Coal

"PERMISSIBLE explosives and dynamite deteriorate with time. They are perishable products. Do you keep them fresh by using the old stock first or do you pile the new explosives on the old and use the new stocks first?" said W. J. German, technical representative, E. I. Dupont de Nemours & Co., at the West Virginia Coal Mining Institute. The Consolidation Coal Co. uses its explosives in the order in which they are received. The old stocks are moved first.

Mr. German said that in his travels he had found a dozen or more fuses as short as 6 to 7 in. long already furnished with caps ready for use. The practice of using such short fuses is not only extremely dangerous, it is wasteful of explosives, it produces an excess of fine coal, but still it goes on. The only sure way to eliminate the dangers of the short fuse is by introducing electric blasting.

As for crimping caps on fuse with knives, files, nails or teeth instead of a crimper, Mr. German said that in so doing the user is taking risks such as the men who manufacture the detonators never take. The men who handle explosives should be as careful as those who make them.

#### INSERT DETONATOR AT END

Miners often make a primer in such a way that the detonator, or cap, extends through the side of the cartridge. When thus arranged the dangerous end of the cap protrudes so that when the latter is pushed back into the hole, the loaded end of the cap bumps and rubs against the side of the hole and it may thus be caused to explode. The safe way is to place the detonator in the center of the cartridge parallel to its length and pointing toward the bulk of the explosive.

If the wires of electric detonators are allowed to drag over the tracks a premature explosion may occur, for a locomotive or a cutting machine may be grounded in a nearby place causing stray currents to pass through the tracks. To tamp a hole and prepare a shot when electric drills and cutting machines are running in the same place is most unwise. This practice is common where the shooting is done at night.

Mr. German graphically described a

trip made into a mine in a car with six miners. The roof was low and cleared the tops of the cars by about 4 in. The miners each had three sticks of explosive in each back pocket and electric detonators in their front pockets with the wires projecting. The rails were poorly bonded. Sparks were flying from the couplings and from some of the bolts in the bottom of the car. The miners were turning and twisting in their uncertain seats causing the ends of the wires to touch the iron work on the car bottom. What would have happened had a stray current passed through the detonator wires? In some of our "well-managed" mines such carelessness is common, and mine superintendents should travel the man trip and note these facts.

#### STORE PERMISSIBLES SEPARATELY

The storing of explosives and detonators in a mine by miners is a source of great danger. Often when the men are cleaning up preparatory to starting pillar work they come across explosives and detonators hidden in the gob by miners who have left and failed to remove them from their hiding places. It is hazardous to store explosives and detonators together. A fall of rock, a lighted match or a spark may set off the detonator and detonate the explosives. Permissible powder stored by itself is not dangerous. Mr. German said he could not imagine any way in which permissibles could be exploded without detonators.

Many a shotfirer with pipe in mouth will open a box of caps, regardless of the danger of exploding the whole box should some of the burning tobacco fall into it. Should he bump his head he may well precipitate pipe and contents into the box. Even a spark from a pipe may fire detonators.

Mr. German closed by calling attention to the unsafe and inefficient tamping of shots due to the failure of the company to provide clay, to the miners' unwillingness to make paper cartridges for the clay, and to the desire to use short fuse. When a man is going to use a skin'emback he usually is wise enough not to stay so long that it will go off before he has had time to get back a sufficient distance, but in his haste the proper tamping of the shot is overlooked.

When holes are bored with electric drills the holes are apt to be drilled deeper than the undercut. This is more common in mines where the coal is shot and drilled by crews at night. In one mine the shooting crews had drilled, tamped and charged as many as fifty holes before the places had been completely cut. Under such conditions the depth of the hole and the quantity of explosives used was a matter of guesswork. This slapdash way of shooting is often the cause of the small percentage of lump coal obtained. The company tries to remedy the matter by changing the powder, but the trouble usually is not in the explosive but in the way in which it is handled.

### Kinloch Miners Never Work With Defective Lamps

By R. C. HITESHUE

Master Mechanic, Valley Camp Coal Co.,  
Parnassus, Pa.

The Valley Camp Coal Co., at the Kinloch slope, Parnassus, Pa., finds it advisable always to send into the mine about thirty extra electric cap lamps to replace any of eight hundred in use that develop imperfections during the working shift. The extra lamps, in numbers from two to five, are carried in a box built expressly for the purpose, as the accompanying illustration shows. These

Nest for Five Electric Lamps

Every motorman is supposed to replace any defective lamps in his district and for this purpose carries a supply on his locomotive.

boxes are loaded onto a supply car and lowered down the slope; then they are distributed, one to each locomotive. When gathering locomotives visit the working place of a miner who has a defective lamp, he exchanges it for one in good condition taken from the lamp box on the locomotive. Several additional boxes are kept at the slope bottom to make sure that a sufficient number of good lamps are available at all times to exchange for those that are defective.

## Practical Pointers For Electrical And Mechanical Men

### Will Set Pump in Operation or Stop It Automatically as Need Requires

Rise of Water Causes Ball to Roll from End to  
End of Runway and Establish or Break the  
Current, thus Starting or Stopping the Pump

At many mines water collects either in sumps prepared for its reception, or in dips, swags or swales in either old or active workings, but from which it must be pumped out periodically. The capacity of the pump or pumps serving such places is greater than the average influx of water, so that these machines are not kept running continuously. The usual practice in some cases at many mines is for the pumpman to make periodic inspections of the various sumps and start and stop the pumps serving them by hand. This is never satisfactory, and the sump is liable to overflow or the pump to run dry if the pumpman doesn't happen to be on hand at exactly the proper time.

In order to overcome this difficulty, the automatic device shown in the accompanying illustration has been devised and has given good results. This device consists of a float *C* hinged to a post at *A*, and so arranged that it may rise or fall through a considerable arc. On top of this float a closed runway containing a steel ball *E* is hinged at *B*. On the forward end of this tilting runway is placed the contact of a switch *F*.

As shown in the illustration, this switch is open and the pump, of course, shut down. Suppose now that the water in the sump, which in this case is a portion of an old roadway, rises 17 in. This will tilt the whole float and the runway upon it to such an angle that the steel ball *E* will roll to the opposite end of the runway. This completes the circuit, starting the pump which will continue to operate until the level of the water has fallen to such a point that the runway *D* is inclined to such an angle that the ball will roll to the end at which it is shown in the il-

Regulates Pump Operation

The rise of the water tilts a runway *D* resting on the float *C* causing the ball *E* to roll to the opposite end of the guide. In its new position it completes the circuit by which the pump is operated.

lustration. This will break the circuit and stop the pump.

A contrivance of this kind can be built by anyone fitted to take care of pumps in the mine. The materials employed in its construction are largely odds and ends that may be picked up about any mining plant, and when properly constructed this device will govern the pump perfectly and without any attention whatever on the part of the attendant. Furthermore, the use of a device of this kind removes the human element from the operation of the pump, holds the water in the sump definitely between predetermined levels and saves much power in pump operation.

### Shape Gage to Be Used on Locomotive Wheels

One of the chief causes for locomotive derailments is defective track. Often the tracks are in bad condition,

Gage for Wheel Tread

Every mine machine shop should be equipped with a gage to be used when old wheels are turned down. Unless the tread is properly shaped, accidents and derailments will occur frequently.

because locomotive wheels are allowed to operate with high false flanges. Almost every time mining men meet and discuss their difficulties, locomotive derailments prove to be the most interesting topic. At a recent meeting one mining man said that some of his derailments were due to the fact that newly turned-down wheels are not always properly shaped. He added that his company is now using a steel gage patterned from the shape of a new factory wheel. In turning down old wheels this gage is used as a templet, and in this way the company is sure that all wheels are properly shaped. This gage is shown in the illustration. It will, no doubt, aid in reducing acci-

dents and delays in other mines when generally adopted.

Another interesting feature in connection with this subject, is the necessity of having all wheel treads alike so that the brake shoes and brake rigging will operate satisfactorily. A turned-down wheel improperly shaped does not afford a brake shoe of standard shape a proper grip. This is no doubt another cause for derailments.

### Bell Sounds When Fan Stops

BY ED GUNIA

Master Mechanic,  
Monarch Fuel Co., Rural Ridge, Pa.

Simultaneously with a power failure or a short in the wiring or control equipment in the fanhouse, a warning should be sounded to notify the electrician or some other plant attendant of this condition. Immediate steps can be taken then either to remedy the existing electrical condition or else switch over to an auxiliary drive unit for operating the fan. In our fanhouse at the Rural Ridge mine of the Monarch Fuel Co., near Pittsburgh, Pa., I rigged up a simple door-bell circuit, with a warning bell in the hoist house, to accomplish this purpose.

Watch the Fan

Some years ago a fan stopped running. Fifteen minutes later the mine blew up and killed everyone in it. This illustration shows how the starter box is made to give warning.

Details of the arrangement are shown in the accompanying illustration. To the operating lever of the starter box I attached a copper contact leaf, and another to the box, these forming two terminals of the circuit. When the lever is in running position, the circuit is open; but when the lever jumps back into neutral, following a power failure or a short, the contact leaves are brought together and the circuit is closed and an alarm is sounded.

### Safe Practice When Using Grinding Wheels

Much has been written about the causes of grinding-wheel accidents. Mishaps do happen occasionally and it is, therefore, the best practice never to operate grinding wheels without the wheel being properly enclosed in a

Protection Flanges

To safeguard the workman every wheel used on the stand should be adequately protected. The operator should also be required to use goggles.

hood. Protection flanges for safeguarding grinding wheels are shown in the figure. A pair of goggles to protect the eyes should also be used. The mine-repair shop operator should take advantage of the safety regulations followed in commercial machine shops. To use the right wheel at the right speed, properly protected, will make it possible to do more and better work.

G. H. RADEBAUGH.

## Keep Underground Machine Shop High and Dry

Did it ever occur to you that when driving a room that is later to be made into an underground machine shop it should be arranged so as to rise and attain such an elevation for the working floor that the bottom of the pit will be higher than adjoining workings? By so doing you are sure to have a machine shop that is always dry, one in which tools and parts are not likely to rust quickly, and where the workmen do not develop rheumatism.

In building the shop all the coal and 10 or 12 ft. of the roof may be removed. With this arrangement the floor can be elevated and still the necessary headroom will be afforded. The machine shop will be approached in this case

by an inclined track resting on bents. Some will prefer to leave most of the coal in place and grade up on it.

The first of these schemes was used in constructing the underground machine shop shown in the accompanying illustration. Both present fire hazards if concrete is not used extensively. The safest and best way is to take out all the coal and brush as much of the roof as is needed to give the necessary headroom, using the roof material in grading to the desired elevation.

## Chain Round Pole Enables Levers to Lift It

Every once in a while about the mines it becomes necessary to pull up a pole, post, stake or pile. Of course several devices such as a jack or tools made especially for the purpose may be employed. As a rule, however, simpler and more inexpensive means may be used.

In the accompanying illustration is shown an extremely simple way of getting a firm hold on a pole with a lever. The attachment to the pole consists of three or more continuous loops of rope or chain. The end of any convenient lever may then be passed through one of the loops. A pull on this loop will tend to tighten the others and prevent their slipping. Of course the lever may be arranged as shown or the fulcrum may be placed between the operator and the pole so that a downward pressure on the end of the lever is required to lift the pole.

If many poles are to be pulled it may be advisable to make, say, two levers, two chains and a series of fulcrums or baits. On the other hand two levers may be used on the same pole simultaneously, one hitching being placed below the other. When the pole has been raised as far as the levers and hitchings will permit it may be held in position by one lever while the other hitching is slacked off and slipped down for a new hold. The pole may then be held by the other lever while the second hitching is readjusted.

As a rule, chain is to be preferred to

Gives Firm Grip on the Pole

At least three turns of rope or chain are taken around the pole. Two of these are pulled up tight and the lever is passed through the third. Lifting on the lever tightens the parts on the pole causing them to grip it securely.

rope for making the hitchings. This may be of either the curb or "log chain" type, some people preferring one and some the other. An old wagon tongue makes an excellent lever for pulling large poles, and for ordinary fence posts or those of similar size a crow bar or piece of drill steel answers every purpose. In wet or marshy land punching a hole down through the ground close beside the post with a crowbar or rod will let the air down to the bottom of the post and make the pulling easier.

## Let Batteries Ventilate and Pump Idle Mine

"The old story that a fleet of storage batteries during a suspension is a liability is certainly not true," states Joseph A. Long, assistant general superintendent and electrician of the Madison Coal Corporation at Glen Carbon, Ill., "for they are proving to be a great asset to us as our monthly payroll shows."

The Madison Coal Corporation, owning one of the largest fleets of battery-equipped locomotives in the country, recently found that, due to a shutdown of one of their mines, sixteen sets of their batteries would not be required for locomotive work.

In most mines, some work must be done whether they work or are idle. Pumps must be operated, the fans must be kept revolving and lights are needed here and there. In the sixteen sets of batteries, which were idle at this particular time, there was an abundance of electrical energy available. All that was required to utilize this energy was proper connection of the cells in series multiple to obtain the required voltage. The batteries were thus connected and this power was harnessed to the machinery which had to be kept running during the shutdown.

Mr. Long states that this unusual application of storage batteries has enabled him to close down the steam plant for 20 days at a time effecting a saving of hundreds of dollars. During this period the batteries, without requiring any recharge, furnished sufficient current to operate all pumps, fans and lights.

Underground Repair Shop with Good Drainage

In this instance the coal was removed and an incline with bents was used for the approach to the repair shop. Any water that may enter the repair pit readily drains out and the shop is kept dry, thus preserving the tools and making the place more healthful for those working in it.

## Discussion

### Commenced Rock Dusting Six Years Ago

Dust Still Visible Though Not Renewed—In Winton Have No Water and Have Used Adobe Dust for Three Years

The use of dust began in an experimental way in the mines of the Union Pacific Coal Co., about six years ago, when the manway at Reliance No. 1 was heavily dusted with adobe. Since that time, no additional adobe has been placed in this manway, but the result of the original treatment is much in evidence, the dust having been carried on down the manway for nearly a thousand feet by the traveling of men and mules.

For the past three years at this company's mines at Winton, Wyo., it has been necessary to resort to the use of adobe dust as a protection from coal dust, for there is no water at Winton and the adobe dust is our only defense. In the summer of 1923, Eugene McAuliffe instructed the local management in Rock Springs to see that dust barriers were placed in all mines. This work has been carried on from that time, the barriers being filled with air-dried adobe dust, 50 per cent of which will pass a 200-mesh screen.

It has been a general practice for many years in the mines of this company to sprinkle haulage-ways, and in the gaseous mines at Hanna and Cumberland, sprinkling was carried into the faces, men being constantly employed on this work alone. At Cumberland, closed lights have been in use for nearly ten years due to the experience encountered in the operation of the property. At Hanna, closed lights have been placed in service during 1923 and 1924, at present all operations at Hanna being under closed lights.

#### DUSTING SCHEDULE ARRANGED

The experience of the bituminous mines in the United States during the past year brought about serious consideration of a general dusting and dust barrier program in the mines of this company, and for the past two months we have been engaged in a general application of sprinkling, dust barriers and adobe dust.

The arrangement of a schedule is now complete. By Nov. 1, of this year, the schedule calls for complete protection of all the mines.

1. In the panel and cross entries, water is to be used on all cutter bars on mine machines and faces are to be wet down. This wetting is to be carried to the mouth of the panel entries and to a distance of 600 ft. from the face of cross-entry work.

2. At the mouths of all panels and cross entries dust barriers containing adobe dust are to be placed. Dust barriers are also to be placed on cross entries between panels and on slopes between entries. This, of course, con-

templates a barrier in haulage ways, air courses, and manways.

3. Slopes and cross entries are being and will be covered with adobe to the depth of from one to two inches, the ribs and roof being washed down in advance of the adobe application, air courses and manways being washed down and then dusted with adobe by means of blowers. These blowers are driven by either direct connected or belted motors.

We have arranged that a specified quantity of the work be performed each month, in order that the mines will be properly protected by Nov. 1, of this year.

Analyses are being made by the Bureau of Mines' laboratory at Pittsburgh, Pa., of the adobe dust we are using. This is done that we may be sure that we are introducing no additional hazard to the health of the men underground.

A. W. DICKINSON,  
General Superintendent,  
Union Pacific Coal Co.  
Rock Springs, Wyo.

### Longwall for Streaky Coal

In the discussion of July 3, a West Virginia operator writes asking for a method of working splint coal of the following average cross section: "Hard slate top, drawslate, 10 in.; fine grade of coal, 48 in., soft slate, 4½ in.; coal, 4½ in.; mixed slate and coal, 5½ in.; coal, 11 in.; sandstone bottom. The soft slate immediately underlying the 48 in. of coal will not support the weight of an under-cutting machine of the short-wall type without the aid of steel skids, and the loader cannot be permitted to use his shovel on the bottom."

A mine having such a bed of coal should be worked by the longwall-advancing system, using the slate for the building of packs, timber cribs being inserted at short intervals. In a section of the mine, a face 100 to 150 ft. wide should be opened and the 4½-in. streak should be cut out by day-wage men with picks as far as they can reach.\* Sprags should be set every 4 or 5 ft. apart. The 4½-in. coal below the slate could then be wedged up, so as to permit the men to increase the depth of the undercut, until it is about 5 or 6 ft. in from the face of the coal. The slate should then be cleaned out, entry and gob packs should be built and the coal shot down and loaded out before the mixed bed of slate and coal is disturbed. By having long faces

\*Why not use a machine?—EDITOR.

the cut can be made more readily in the slate seam and it will be easier to lift the mixed slate and coal.

WILLIAM BARLOW, SR.  
Landgraff, W. Va.

### Walsh Does Not Oppose Trolley Locomotives

I request the courtesy of space in *Coal Age* to correct a wrong impression that may be created by the special dispatch from Scranton, Pa., June 27, published in the issue of July 3 of *Coal Age* in which reference is made to the report of the mine inspectors who investigated the explosion at the Loomis Colliery of the Glen Alden Coal Co., June 6.

The writer of the special dispatch states that:

Among local coal-mining men it is thought that the inclusion of the electric trolley locomotive as a cause of the explosion may have been written into the report by the mine inspectors to aid Secretary Walsh in his campaign against the use of electrically operated machinery in underground workings. Mr. Walsh has time and again protested against the operation of such equipment as electric trolley locomotives.

I desire to say most emphatically that I am not against the use of electrically operated machines in underground workings, but what I do oppose is the use of trolley locomotives or any other open type of electrically operated motor in sections of mines where the atmosphere may become highly explosive in a short time as a result of an interruption of the air current.

The report to which reference has been made was written by some of the best qualified men in the anthracite region, and in that report they put their own independent judgment.

JOSEPH J. WALSH,  
Secretary of Mines.  
Harrisburg, Pa.

### Should Air Space Be Used With Black Powder?

We use black blasting powder at our mines. Would it be safe to use the air-space method or to place a loose dummy on the charge? Experiments by J. F. Burgone showed that with a 2-in. drillhole 20 in. of tamping are required. I have always found that black blasting powder would give good results when tamped tight and hard. Of course with a high explosive a better quality of coal is produced by this method of charging, but would it be equally available with black blasting powder?

JOHN W. JONES.  
Altoona, Ala.

Although the reports on the cushioned method of blasting with black powder are rather limited, the Hercules Powder Co. can advise you that the few reports it has received indicate that the cushioned method of blasting is effective also with black blasting powder. The air space between the powder and the tamping probably should not be as great as with high explosives, but it would be well to try out its effectiveness in every instance.

J. H. HORLICK, JR.  
Manager Service Division.  
Hercules Powder Co.,  
Wilmington, Del.

# Production And the Market

## Strong Tone Prevails in Bituminous-Coal Trade Despite Small Volume of Business

Save for occasional nibbles in the way of scattered inquiries, tangible evidence of an early pick-up in the bituminous-coal trade is as hard to find as ever; nevertheless the unquenchable optimism evinced in certain quarters of late will not down. Actual orders are few and far between, working time at the mines is short, yet several mines in the eastern Ohio field have opened recently and preparations are going forward for further resummptions. Despite the absence of visible support for the favorable sentiment, most centers report an improvement in undertone, attributable probably to the certainty that the longer the depression lasts the more inevitable it becomes that there will be an upturn and that it will not be an evanescent flurry. Considerable strength has been imparted to this feeling of confidence by the prosperity of the agricultural industry, fine crops and increasing prices being the rule.

### Loader Scale Means More Union Coal

The signing of a machine-loader scale in Illinois was the outstanding event of recent weeks, presaging as it does keener competition from union operations by reason of the resultant decrease in production costs. Although a strike of cutting-machine runners has delayed operation under the new scale, it is confidently believed that an adjustment will soon be reached, when the effect on market conditions will be watched with interest.

Coal Age Index of spot prices of bituminous coal registered no change during the last week, standing on July 28 at 163, the corresponding price being \$1.98.

There has been a falling off in activity at Hampton Roads, dumpings of coal for all accounts during the week ended July 24 totaling 343,060 net tons, a decline of 30,540 tons from the preceding week, when 373,600 net tons was handled. The movement of coal to the lakes is proceeding pretty much in its accustomed groove for this season, dumpings at Lake Erie ports during the week ended July 27, according to the Ore &

Coal Exchange, being as follows: Cargo, 785,817 net tons; fuel, 43,443 tons. The totals for the previous week were 733,634 net tons of cargo coal and 41,667 tons of fuel coal.

Production of bituminous coal reacted slightly during the third week in July, output during that period, according to the Geological Survey, totaling 7,403,000 net tons, compared with 7,502,000 net tons during the preceding week, according to revised figures. Anthracite production also fell off during the week ended July 19, 1,840,000 net tons having been turned out, a decrease of 31,000 tons from the previous week.

While anthracite production is holding up well not much of it is finding its way to the consumer's bin, as the demand in the leading markets is sluggish for both domestic and steam sizes. A fair movement to New England is aiding materially in maintaining independent prices, though concessions have been necessary in some instances to keep tonnage moving. Stove continues to command top prices, 25 to 50c. being lopped off when egg or chestnut is taken with it. Pea moves slowly, if at all, much of it going into storage piles, and buckwheat is markedly draggy. Retail yards are well filled, consumers evincing scant interest in next winter's coal requirements.

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Improves Slowly

No great change in the coal market was noticeable throughout the Midwest region during the past week. A slight but steady improvement of tone, especially in the country trade, made itself felt here and there. The main disadvantage of this is that it makes too many operators hanker to reopen closed-down mines, thus killing the new flower with overcultivation. This has been going on so persistently for several days that the contemplated increase in the price of Illinois domestic sizes Aug. 1 has been given up. There is very little likelihood of any change in circulars. Smokeless and anthracite domestic business continues sluggish.

Railroads continue taking a little coal steadily on low-price contracts—many of them short-time agreements—but other steam business is slow.

Running time throughout the fields of southern and central Illinois has been so short during the week that "no bills" have increased somewhat. Southern Illinois screenings now hardly ever top \$1.75, although not much moves at less than that. There is much suffering among miners and their families. No field in Illinois is in even fair condition. A little railroad and small industrial and domestic trade are all there is.

In St. Louis domestic trade is still flat. Anthracite and coke storage, usually definitely on the pick-up by this time of year, remain slow. There is a little tonnage moving in the cheaper grades for current use where gas is not available. Steam business in the city, both wagonload and carload, is quiet. The only life is shown in country domestic, and this is little enough. There are no changes in prices worthy of note.

### "Slightly Better" in Kentucky

The coal trade in Kentucky is admitting slightly better business, but kicking on prices. The retailers are buying sparingly, for immediate needs only, and total production of prepared coal is still low enough to prevent any overproduction of screenings, which means that there is no cause for advancing prepared prices or lowering screenings. The fact that lake movement hasn't been as heavy as anticipated has curtailed overproduction of eastern Kentucky screenings. However, eastern Kentucky has been producing a considerable amount of coal in the Elkhorn or Northeastern fields, along with the Hazard and Harlan regions, all of which show good operating time.

Although there has been a good deal of wage reduction in eastern Kentucky fields, it must be admitted that prices are quite low for this season of the year. Peak prices are

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924		1923	
	July 28	July 21	July 14	July 28
Index .....	163	163	162	196
Weighted average price.....	\$1.98	\$1.98	\$1.96	\$2.37

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

around \$2.50 a ton, while the lowest quotations available are on eastern Kentucky screenings, at a low of 85c.

The western Kentucky market continues firm, with slightly better demand reported. It is said that such companies as are operating union mines are getting better production for their wage scale than at any previous time in years. It also is asserted that in some of the operating mines there are indications of private agreements and slight cutting of wage scales, while in some other mines full wage scales are paid, but only on private agreements relative to increased production per day.

Smokeless prices show signs of weakening, particularly in Western markets. Production has not been affected perceptibly, however. The price of high-volatile lump and egg also has receded in inland markets. The market for domestic coals is extremely sluggish. Upper Potomac conditions are such that there has been no change in prices on the various grades.

### Northwest Looks for Action

Little life was shown in the Duluth market during the week, except a general better feeling and a firming of prices, which is particularly noticeable. The selling movement is no better than it has been, in fact the dock men are living on hopes for the future, but they believe that two or three weeks will see an end to the inactivity. The majority of the coal which is moving from the docks now is railroad coal, and it is thought that the railroads will have their own supplies well out of the way before winter.

Anthracite is being shipped to Winnipeg from the three

Duluth docks which have rail connection with the Canadian Northern. In fact Canada is the best hard-coal customer in this market at present.

The movement to the docks picked up this week, when 37 cargoes were received, of which seven were hard coal, and 20 cargoes are reported on the way, of which five are of hard coal.

Warm weather at Milwaukee serves to check what little business the coal men have been doing of late, and the market is very dull. Country dealers are evincing some disposition to lay in stocks, but the industries are out of the market at present. Prices continue unchanged. Lake receipts have slowed up considerably. Thus far this season 347,238 tons of anthracite and 844,318 tons of soft coal have arrived at Milwaukee.

### West Does Fairly Well

A steady though slight increase in business through the Southwest presages the opening of the fall demand. Kansas strip coal, which has been selling for \$3.75 for lump, \$3.50 for nut and \$2.75 for mine run, again is quoted at the same price as shaft coal. The price of Henryetta (Okla.) coal, slashed during a recent fight among Oklahoma operators for business, has been advanced 50c., as the market improves. It now is quoted at \$4.50 for lump, \$3.75 for nut, \$3.25 for mine run and \$2 for screenings. Some operators already have increased their price for Arkansas semi-anthracite. The increase is expected to become general early in August. As a result of the uneven advance, Arkansas coal is quoted \$5.50@\$7 for lump, \$3.25@\$3.75 for mine run and \$1.75@\$2 for screenings. Kansas coal is \$4.50 for lump, \$4 for nut, \$3.25@\$3.50 for mine run and \$2.50@\$2.75 for screenings.

Reports on the Colorado coal market activities show very little change from last week. There is little demand for anything. Mines worked on an average of only sixteen hours last week and a number of them report unbilled loads on track. The operators' weekly reports show more than 50 per cent of the working time lost was attributed to "no market."

In Utah more coal is being mined and sold than a few weeks ago, but mines are still working less than three days a week. Lump is moving for domestic storage, but so are most other sizes. The principal industries buying coal are cement plants, sugar companies and metal-mining companies. Railroads are taking very little, but they are not entirely out of the market.

### Cincinnati Market Drags

Little change is to be noted in the dull and draggy condition of the Cincinnati market. Even the slack market, which showed signs of coming to life with the continued reduction in the make of prepared sizes, has settled back again. The one bright spot in the bituminous list is run of mine, which, in spite of some rough knocks recently, holds consistently and with an evidence that this, at least, has struck rock bottom. Smokeless business is of the in and out order. The end of the month finds prices hardening a little. Inquiries from steel plants and concerns with malleable requirements begin to show a better vista ahead. Retail prices are unchanged and in keeping with the mid-summer inactivity. Specialized coals are quoted as follows: Egg, \$2.25@\$2.75; block, \$3@\$3.75.

A better feeling is developing at Columbus. This is more psychological than real, as few operators or jobbers note any increase in business. While some steam consumers still have fair stocks, the amount of fuel above ground has been reduced materially. There is still a considerable quantity of demurrage coal and consequently some low quotations are heard. Contracting is not active, although an occasional agreement is being renewed. Domestic consumers are still playing a waiting game and dealers' business is rather light. Coal is moving in larger quantities to schools and municipal and county institutions. Lake trade is quiet although reports show a congestion of loaded cars between Columbus and Toledo. West Virginia mines are supplying the main tonnage for lake shipment.

A slightly improved tone has developed during the past ten days in markets served by eastern Ohio mines, output having increased. Cleveland industries, however, continue to work less than half time in many instances, and consumption of steam coal is more or less restricted. The additional tonnage consists of miscellaneous lots placed

here and there. Several mines have resumed operations in the eastern field, and retailers are becoming a little more active.

Dullness persists in the Pittsburgh market. Production is chiefly under special conditions, the coal not moving through the open market. Slack is a regular commodity, and in consequence it shows occasional slight price changes. The industrial outlook in the district appears somewhat improved.

Little improvement is noted in mining conditions in the central Pennsylvania field. For the week ending July 19 the loadings were 11,172 cars, as compared with 10,804 cars in the previous week. There are 2,000 no-bill cars reported in the district.

Trade at Buffalo is still pretty quiet. Nothing would produce good prices except a car shortage or a strike, and neither is in sight now.

### Inquiry Light in New England

In New England the outlook for steam coal continues anything but favorable. Prices are as low as, and in certain instances even lower than, at any time this season, and inquiry is relatively so light that forcing coal is still indulged in by several of the agencies. Steamer rates from Hampton Roads are about 75c. to Boston, and with this added to \$4.25 per gross ton f.o.b. vessel at Norfolk or Newport News it is easy to account for a range of \$4.35@ \$4.40 per gross ton on cars for inland distribution. The territory is being scoured for spot orders, and there is enough business to absorb what tonnage arrives.

Moderate accumulations are the rule at Hampton Roads. In some quarters there is really drastic curtailment, but in others there is a disposition to chase rainbows and open the gate on the strength of sporadic sales. There are occasional commitments being made off-shore, and these together with certain staple tonnage are sufficient to keep the average movement up to the May and June level.

All-rail there is no material change. In certain of the non-union sections of central Pennsylvania there are renewed differences with labor over the wage scale and incidental problems. The undependable market is responsible for fluctuations in output, a situation that is difficult for all concerned. Prices are about as low as they can go without cutting too deeply into actual costs, and even the highest grades are being offered at figures little above those quoted for ordinary Beech Creek coals. Dumpings over the Philadelphia and New York piers continue extremely light, and except for specialties there is only a most restricted outlet for steam grades via this route. Hampton Roads shippers have very much the advantage both as to base cost and marine rates.

### Atlantic Seaboard Consumers Indifferent

Lack of interest features the New York market. There is comparatively little buying, most of the coal coming to tidewater already on contract. More coal is being shipped to the local piers than is really necessary to meet requirements, owners letting it go at figures below current quotations in order to save demurrage charges. Fading reserves and an increase in inquiries give some hope that better buying is close at hand.

Inquiries are comparatively plentiful at Philadelphia, but it is another matter to translate them into orders. Industrial conditions have not improved, yet reports are plentiful of certain textile concerns expecting to operate more fully, and some of the iron concerns also are showing hopeful signs of improvement. Prices remain firm and

practically unchanged. Tide conditions have eased again after a little flurry a week ago.

The situation at Baltimore continues dull and uninteresting, there having been practically no change for over two months, except for spasmodic periods of inquiry. The betterment of conditions hoped for with the gradual depletion of stocks has failed to materialize, and from practically all sources come complaints of general flatness in home trading. The records for the first three weeks of July show that the export trade is well in advance of that of the first three weeks of June.

Lack of a supporting market has brought production in the Birmingham district to the lowest figure recorded in many weeks, 308,000 net tons being reported for the week of July 19. There is a mere dribble of spot business being taken on. Industrial conditions are very unsatisfactory, and consequently only fuel necessary to a very restricted operation is being provided. Much of the contract domestic tonnage is being held up, as the retail market is sluggish and little coal is moving from the yards.

### Anthracite Trade Lacks Life

Demand for anthracite at the New York tidewater is almost lifeless. Retail yards are nearly filled, consumers being either on vacation or not showing any desire to fill empty bins if they are without next winter's coal supply. One shipper, commenting on the local situation, said that he had sold more than 10,000 tons of hard coal within the last week, all of which was to line customers, and that during the same period he had not sold anything at tide-water. New England continues to take its share of anthracite and this has helped to maintain quotations for independent coal on something like last week's basis, although some shippers have found it necessary to quote lower figures in order to keep tonnage moving. The better grades, however, bring the maximum prices quoted. Straight lots of stove coal are bringing top prices, but when this size is taken with either egg or chestnut, from 25c. to 50c. is taken off. Pea coal moves slowly and is being stored by nearly all operators. Producers find it difficult to dispose of the smaller coals. Buckwheat is particularly hard to move and only the very best grades bring the highest prices. Rice and barley move easier.

Philadelphia dealers' yards are filled to saturation, and many producers will find it a problem to operate in August. Buying is so slow that during the past week the lightest tonnage was moved for any similar period in the past seven years. The steam trade also is still slow, and independent shippers are moving output only at cut rates.

It is difficult to perceive any change in the hard-coal situation at Baltimore. The trade reports a dull demand, and there is little expectation of a material change for some time to come.

The Connellsville coke situation shows no change of consequence. Demand and production are extremely limited. Production of beehive coke during the week ended July 19, according to the Geological Survey, totaled 105,000 net tons compared with 106,000 tons during the previous week.

## Foreign Market And Export News

### British Coal Markets Unsettled; Output Passes 5,000,000 Tons

The Welsh steam coal market is still very unsettled and business on the whole is poor. Buyers both at home and abroad are extremely cautious and a state of great uncertainty is plainly evident. A depreciation in the reparation currencies is reflected in a falling off of the European demand, and business in South America is getting more and more difficult to obtain. Many domestic buyers and coaling stations are buying very slowly, anticipating a fall in the prices of the best coals.

The inquiry in Newcastle for best steams and gas coals has improved a little over last week, but the remainder of the market is stagnant. Supplies are abundant and many pits in the Durham area are on short time in consequence. There are no contracts worth reporting. Buyers who desire prompt deliveries are obtaining concessions.

The output of the British coal mines during the week ended July 12, a cable to *Coal Age* states, was 5,002,000 tons, according to the official reports. This compares with 4,988,000 tons produced during the week ended July 5.

### Trade at Hampton Roads Weak In All Branches

Business at Hampton Road is poor, with the market weak and buyers rare. The Raleigh Smokeless Coal Co. has renewed its old contract for South American shipments, chartering vessels to make deliveries, which were figured about \$4.25-\$4.35 f.o.b. piers.

Spot export business is almost non-existent and bunkers and coastwise trade have reached a low level. The trade had expected dullness in bunkers and coastwise, but there is some disappointment at the falling off in foreign business.

Movement of South American coal constitutes the bulk of the activity, although a few cargoes are going to Canada and other nearby countries.

The tone of the market is weak, and the trade is not optimistic over the immediate future.

### United States Domestic Coal Exports During June

Value.....	\$10,645,522	\$6,582,238

### Industrial and Domestic Trade Slow in French Coal Market

Industrial coal is plentiful, due to slackening of demand. British coals, although weaker at the shipping docks, are more expensive than the French product on account of the rate of exchange. The volume of orders for household coals at the mines is good, but dealers report the consumer demand weak save for a slight flurry toward the end of the month.

Deliveries of indemnity fuels during June to the Office des Houillères Sinistrées for France and Luxemburg consisted of 201,970 tons of coal, 537,517 tons of coke and 26,908 tons of lignite briquets, a total of 766,395 tons. Receipts were larger than during the previous month but still much lower than before the strike.

The O.R.C.A. is receiving coke at an average rate of 16,174 tons daily. The price of coke remains at 150.75 fr. frontier station Sierck (all O.R.C.A. charges included).

Production by French mines during May consisted of 3,615,910 tons of coal, 76,890 tons of lignite, 220,100 tons of coke and 242,732 tons of patent fuel, a total of 4,155,542 tons. This compares

with April output of 3,565,225 tons of coal, 75,572 tons of lignite, 215,056 tons of coke and 250,908 tons of patent fuel, making a total of 4,106,761 tons.

## News Items From Field and Trade

### ALABAMA

Several of the big coal-mine owners of the Birmingham district are contemplating the general use of limestone dust for sprinkling in the mines to minimize the dangers of coal-dust explosions.

Preparations are under way for the fall meeting of the American Institute of Mining and Metallurgical Engineers, which will be held in Birmingham, Oct. 13-15. Several interesting papers are being prepared by coal-mine executives and engineers covering mining methods used in this district and the process of washing and preparing coal for the market and for use in coke manufacture.

### COLORADO

The Alamo Coal Co. is about to begin the erection of 21 buildings at its plant near Walsenburg.

The Three Pines Coal Co., of Val-lorso, employing about 80 men, has filed with the State Industrial Commission a notice that it purposes cutting wages 25 per cent Aug. 1. The men were expected to file a protest which would result in a commission hearing.

### ILLINOIS

The Sunnyside mine near Herrin is shut down again. This time the tie-up is because of an argument over the payroll. The Burton Coal Co. took over the mine during June after Anderson & Roberts had failed to meet pay-rolls during May. The miners claimed a total of \$51,000 was due them. The Burton Coal Co. made an agreement with the men and the mine resumed. But after July 15 the men refused to work longer, asserting that the Burton company had not fulfilled the agreement.

Practical tests of Prof. S. W. Parr's process of coking Illinois coal have been started at the University of Illinois, at Urbana. First-run tests, it is believed, will demonstrate the effectiveness of his low-temperature process and prove that Illinois coal can be made into coke by that method.

The movement for greater mine safety in Illinois may be advanced by the activity which grew out of a regional safety meeting held in St. Louis, Mo., in June under the direction of the National Safety Council. A committee appointed then by D. D. Wilcox, of the Superior Coal Co. of Gillespie, met July 17 in Springfield to plan the next step toward a new state-wide safety council.

The Governor will be asked to call an Illinois mine safety meeting in November. An executive committee to be in charge of the meeting is headed by Martin Bolt, director of the State Department of Mines and Minerals. W. D. Keefer, of the National Safety Council, is secretary. Mr. Bolt has not yet appointed the other members.

Fire of unknown origin recently caused damage of approximately \$15,000 at the Kelly No. 4 mine of the United States Fuel Coal Co., located east of Westville, and about ten miles southeast of Danville. The fire destroyed the boiler room, engine room and the tipples. This mine has been a big producer for nearly twenty-five years. The mine was sunk in 1901 and operated continuously, except for brief shutdowns, until May 22, 1924, when the mine was closed. The mine for years gave employment to about 650 men.

### INDIANA

The coal properties of the New Discovery Coal Co. and the Parke County Central Coal Co., both located in Parke County, will be sold at a receiver's sale soon. The properties consist of leases on more than 500 acres of semi-block coal, shafts, tipples, buildings, boilers, engines, machinery, cars, scales, tools and other mine equipment. The Rockville National Bank is receiver for the two companies.

The controversy between Terre Haute miners and the Chicago, Milwaukee & St. Paul R.R. over the Blackhawk miners' train will be heard soon by the Indiana Public Service Commission. The trouble began four years ago, when the service commission issued a ruling regarding a miners' train to be run between Terre Haute and Blackhawk to accommodate miners. The ruling then said when a train should leave each terminal. The railroad followed these instructions until work became dull, when it attempted to change the schedule to three days a week. The union lodged a complaint. Three weeks ago the railroad issued an order that the train be discontinued altogether and that the miners' coaches be attached to the early morning and evening trains operating between these points. Again the miners objected.

Stripping mines in Pike County are being worked nearly every day while the shaft coal mines are operating only two and three days a week. The Indiana strip-pit operators are said to be meeting Kentucky competition successfully. It is reported that more than 2,000 miners in Pike County, unable to

work sufficiently at their regular vocations, have turned to others, saying they intended quitting the mines for all time.

A total of 12,289,296 tons of coal was mined in Indiana in the first half of the fiscal year of 1924, according to a report by Cairy Littlejohn, chief state mine inspector. The report shows that \$20,932,231 in wages was paid to Indiana miners during this period. The total amount of wages for all the last fiscal year was \$45,920,877. The number of employees for the first six months of the present year, as shown in the report, totals 23,861, as compared with 31,189 for all of last year, a sharp reduction reflecting the low output of the Indiana fields.

### KANSAS

William S. Anderson, vice-president of the McGrath Coal Co., suffered a fractured arm, several fractured ribs and severe bruises when he slipped and fell from the top of a 12-ft. tank at the company's mine near Pittsburg July 15.

Two of the large companies of the Kansas coal field have departed from the long followed custom of paying the miners cash. The Western Coal & Mining Co. and the Clemens Coal Co. are now paying by check to avoid the danger of payroll robberies. Checks are distributed two or three days earlier than the regular pay day.

The Western Coal & Mining Co.'s Mine No. 20, West of Arma, set a new state record for shaft-mine coal production July 15 with 1,529 tons for an eight-hour period. J. D. Delaney, superintendent of the Western, said he hopes to climb to the 2,000-ton mark. The former high mark in this district for an eight-hour period was 1,446 tons, held by a mine of the Central Coal & Coke Co. Western No. 20, which is 215 ft. deep, is equipped with the latest machinery and employs about 300 men.

### MINNESOTA

The Great Northern Ry. has started a series of tests of the use of lignite used in powdered form and dried and blown into the firebox all at one operation. The tests are being made at the Dale Street shops in St. Paul, Minn. Including all in one operation, eliminates the need of storing the pulverized fuel and does away with the danger of explosion. If the tests prove a success, the method probably will be adopted at the company's shops in North Dakota and eastern Montana. The tests may include locomotives.

Courtesy U. S. Distributing Corp.

### Mining Village of Dietz, Wyo., Sheridan-Wyoming Coal Co.

An unusual quantity of foliage for Wyoming is to be seen in yards of these houses, which as will be noticed have only one story.

## MISSOURI

The St. Louis office of the Bureau of Mines was discontinued on July 1, 1924. C. E. Van Barneveld, superintendent of the Mississippi Valley Station, Rolla, Mo., with which the St. Louis office was connected, has resigned. B. M. O'Harra is acting as superintendent of the Rolla Station.

The Missouri Public Service Commission on July 21 issued an order denying the application of the West Missouri Power Co. for authority to purchase stocks and bonds of the Fort Scott & Nevada Light, Heat & Power Co. and coal mines and equipment belonging to the Clinton Coal & Mining Co. It proposed to purchase \$800,000 par value common stock of the Fort Scott & Nevada company and \$450,000 par value of its first mortgage bonds for \$645,000 and the mines, equipment, etc., of the coal-mining company for \$200,000. The commission held that the purchase price was excessive compared with the value of the property to be purchased.

## NEW YORK

The Pennsylvania Coal & Coke Corporation reports a deficit before federal taxes, for June of \$54,595, as compared with net earnings of \$32,685 for June, 1923. The deficit, before federal taxes, for the six months totaled \$141,108, as against net earnings of \$582,000 for the corresponding period last year. The six months' gross was \$3,030,855, as compared with \$4,558,389. The company declared the regular quarterly \$1 dividend, payable Aug. 11 to stock of record Aug. 5.

The Virginia Iron, Coal & Coke Co. reports a net loss of \$51,199, after interest and taxes for the quarter ended June 30, 1924. This compares with a net income of \$5,792, equal to 11c. a share, earned on the \$5,000,000 preferred stock in the preceding quarter and a net income of \$114,984, or 52c. a share, earned on the common stock

in the second quarter last year. For the first six months of 1924 the net loss amounted to \$45,406, as compared with a net income of \$358,543, or \$2.33 a share on the common stock, in the first half of the previous year.

## OHIO

The Southern Ohio Coal Exchange reports for the week ending July 12 an output of 79,370 tons from 439 mines in the southern Ohio field. The full-time capacity was 645,430 tons which leaves a shortage of 566,370 tons. Labor shortage caused a loss of 3,995 tons; strikes, 8,580 tons; mine disability, 4,180 tons and "no market" 549,305 tons. During the same week the eastern Ohio field ordered 10,650 cars and loaded 7,739 cars.

The M. A. Hanna Co., Cleveland, which operates iron-ore mines, anthracite and bituminous-coal mines, announces the issue as of Aug. 1 of \$7,000,000 ten-year sinking-fund gold debentures. This is part of an authorized issue of \$15,000,000 and will be a direct obligation of the company. The debentures are being marketed by Dillon, Read & Co., New York City, and the Union Trust Co., Cleveland. The introductory price is 98½ and accrued interest, to yield more than 6.20 per cent.

Plans are being formulated for the state safety meet at Bellaire, Aug. 16, when a campaign will be started to eliminate accidents in coal mining and allied industries. Manufacturers are invited to attend the demonstrations, and invitations are being prepared by the Bellaire Chamber of Commerce, the city's mayor, the United Mine Workers of America and Joseph A. Holmes Safety Association. Exhibits in safety and accident prevention work deal not only with the coal-mining industry, but will be of interest to all employers of labor.

The Hocking Valley R.R. was compelled on July 22 to place a temporary

embargo on the movement of lake coal onto its lines, owing to the fact that between Columbus and Toledo there are over 5,000 loaded cars awaiting handling at the Toledo docks. The congestion of the coal, an unusual condition for this season of the year, is due to the withdrawal of several boats ordinarily used in transporting coal to the upper lakes. This coal is coming from the non-union mines of West Virginia and Kentucky. Practically no coal is moving from southern Ohio mines to the upper lakes.

## PENNSYLVANIA

The H. C. Frick Coke Co. is very materially increasing output from the three Colonial mines at Grindstone and Smock, from which plants the coal is transported on a five-mile belt conveyor system to the Monongahela River. The Hillman Coal & Coke Co. has closed down indefinitely the Pike Mine, a union operation near Brownsville, on the edge of the coke region, but is increasing shipments from its non-union operations, where the wage scale has been reduced.

The departure of S. J. Phillips, of Scranton, for a trip abroad makes five vacancies among mine inspectors in the hard-coal fields, four having died. Mining companies, asked by the Governor and the state mine chief to cut down accidents, will not get the same inspection precautions from a depleted corps.

Because the officials of the Evans Colliery Co. at Beaver Meadow refused to dismiss Frank Satechick, of that town, a locomotive engineer, who, it is alleged, refused to pay a union fine of \$50, two hundred men went on strike.

Increased taxes paid by the Quemahoning Coal Co. for the year 1922 on mineral holdings in Jenner township, Somerset County, will be refunded under a decision of the Pennsylvania Superior Court handed down on July 3, in which the Somerset County Court was reversed. The decision also affects a number of other coal companies holding land in Jenner township. Two years ago, in making the triennial assessment, valuations on coal holdings were materially increased. Some 1,500 appeals were taken and subsequently the County Commissioners revised the assessments downward. The road supervisors and school directors, however, used the higher valuations as certified by the County Commissioners. Legal proceedings were started to prevent the collection of the higher taxes and the Somerset County Court decided in favor of Jenner township. The superior court has reversed this decision. The decision in the Quemahoning case will affect a large number of other cases in Jenner and other townships.

The Haddock Coal Co., composed of Schuylkill County, Philadelphia, New York and Wilkes-Barre capitalists, will expand its operations, it is announced. The company is the lessee of the Silver Brook workings, where an output of 3,000 tons a day is predicted when extensive development work now in progress.

ress is completed. Slopes are being sunk and machinery is arriving and being assembled for a breaker on a coal property near Youngs Landing, Pottsville.

S. D. Warriner, president of the Lehigh Coal & Navigation Co., the Alliance Coal Mining Co., the Cranberry Creek Coal Co. and the Panther Valley Water Co., announces the appointment of Edward Hughes, formerly purchasing agent, as comptroller, vice E. M. Reynolds, deceased. J. R. Bennington, formerly assistant purchasing agent, has been appointed purchasing agent, vice Edward Hughes.

Fire of unknown origin on July 20 at Claridge, a small mining town of the Westmoreland Coal Co., near Jeannette, caused the death of two children and wrought damage estimated at more than \$50,000.

Making a perfect score in the elimination contest held July 17 at the Prospect colliery, the Red Ash first-aid team of the Prospect colliery, Lehigh Valley Coal Co., won the right to represent the Susquehanna division in the annual first-aid meet of the company to be held at Hazle Park in August. Twelve teams, representing the Prospect, Henry and Dorrance collieries, were entered.

The car-repair shop at the Audenreid colliery of the Lehigh & Wilkes-Barre Coal Co. was destroyed by fire July 20. The loss is estimated at more than \$10,000.

## UTAH

The general offices of the United States Fuel Co. and its Utah coal sales agency, of which Moroni Heiner is vice-president and general manager, are now located on the tenth floor of the Newhouse Building, Salt Lake City.

## WASHINGTON

William Shaw, formerly superintendent of the Roslyn Fuel Co. mines at Jonesville, has entered the mine supply business at Seattle. Robert Scobie, Jr., of Cle Elum, is the new mine superintendent at Jonesville.

It is expected at Buckley that the new Black Carbon mine, near there, will begin producing coal during August. The tippie is nearly finished and underground development, from a 35-per cent slope, is extensive enough to justify an output of 300 tons a day during the winter.

## WEST VIRGINIA

The Board of Directors of the Consolidation Coal Co. has declared a quarterly dividend of \$1.50 per share on its common capital stock, payable July 31, 1924, to the holders thereof at the close of business July 15, 1924. The transfer books will remain open. Dividend checks will be mailed.

In the second annual inter-mine first-aid meet of the Bethlehem Mines Corporation the Masontown team won the contest. There were teams from five different mines entered in the contest. Composing the Masontown team

were J. C. Everly (captain), Harry C. Brown, Carl Watson, T. E. Titchwell and W. N. Williams. The Bretz team composed of Edward J. House, captain, Arlie House, Edward Booley, Rex Doddridge and Guy Shuck, took second place. The Masontown team, which wins the district cup, will go to Johnstown, Pa., to participate in the company's general safety meet and will later participate in the state meet at Wheeling. The Masontown girls' team won the girls' contest. The girls' team includes Zeda Snyder (captain), Virginia DeBass, Madaline McCall and Sarah Cornelius.

So many former employees have violated a recent injunction obtained by the Brady-Warner Coal Corporation that the corporation has caused to be issued an order summoning nineteen men living at Brady and in that vicinity to appear before Judge I. G. Lazelle to show cause why they should not be adjudged guilty of contempt of court for violation of the injunction issued by Judge Lazelle on May 23. Three men who were arrested on June 25 for violation of the injunction have been released with the understanding that they will present themselves before the court when ordered to do so.

R. M. Lambie, chief of the State Department of Mines, has announced a number of meetings for the purpose of talking over safety measures and getting suggestions as to changes that may be necessary in the mining laws to make them conform to modern mining methods. All suggestions are to be compiled and carefully gone over by a commission appointed by the Governor for that purpose. The meetings will be held at the following places at 2 p.m. on the dates mentioned: Beckley, High School building, Aug. 1; Welch, school building, Aug. 12; Logan, High School building, Aug. 15; Wheeling, High School building, Sept. 3. A meeting was held in the Fairmont Hotel, Fairmont, July 23 and at Central Junior High School, Charleston, July 29.

## CANADA

An explosion at the Allan shaft of the Acadia Coal Co.'s mine at Stellarton, N. S., recently killed four men and injured several others. There were 74 men in the mine when the explosion occurred. Sixty three were in the shaft and escaped without difficulty. Eleven men were behind the barrier formed by a cave-in following the explosion, which occurred on the 1,200-ft. level. After four had died from suffocation or from shock, the remainder were saved by breaking the fresh-air pipe line running through the shaft. A rescue party discovered an unused passage leading to the gallery where the men were imprisoned and, cutting through a thin partition of earth, released them.

John Sowards, head of the Sowards Coal Co., Ltd., Kingston, Ont., has left for Glasgow, Scotland, where he will purchase several vessels to be used in the lake coal-carrying trade in Ontario.

Forty employees of the official and clerical staffs of the Dominion Coal Co.,

Glance Bay, N. S., were cut off the company payroll July 1, and it is understood that other sweeping reductions are to be made in all departments of the company. Depression in the coal trade was the reason given.

The Dominion Government has suspended the duty of \$1 per ton upon imports of coke. The change was made at the request of the fruit farmers of western Ontario, who are anxious to preserve their surplus crops by drying them.

The Toronto Wholesale Coal Dealers' Association has been advised by the Dominion Government that the former dumping regulations which were applied against coke have been withdrawn. The duty has been revoked.

## New Companies

The Consumers Fuel Co. has just been organized by Ohio County people with a view to operating in the northern Panhandle. This company is capitalized at \$250,000, with general offices at Wheeling. Principally interested in the new concern are H. R. Stone, W. R. King, William J. Gompers, Charles J. Schuck and R. A. Breese, all of Wheeling.

The A. J. Stewart Coal Co. has been launched by men prominent in coal circles of southern West Virginia. This company is capitalized at \$150,000, its principal office being at Bluefield. Chiefly interested in the new company are A. J. Stewart, J. H. Hoge, R. L. Bailey, J. Paul Stewart and E. L. Bailey, all of Bluefield, and W. S. Wray, of Northfork.

New coal companies having a total capitalization of \$797,500 were launched in West Virginia during June, as follows: Charter Coal Co., of Morgantown, \$100,000; Byford Big Vein Coal Co., of Elk Garden, \$25,000; Consumers Fuel Co., of Wheeling, \$312,500; Troy Camp Coal Co., of Clarksburg, \$110,000; Christiana Coal Co., of Charleston, \$50,000; A. J. Stewart Coal Co., of Bluefield, with chief works in Kentucky, \$150,000; Oliver Fuel Corporation, of 902 Fox Building, Philadelphia, Pa., \$50,000.

A new company has been organized at Rutland, Ill., to operate the coal mine there. The company is incorporating with a capital stock of \$150,000. The company will be known as the Rutland Third vein Coal Co. Those forming the organization are J. L. Bane, Fred W. Sauer, Loyus Gowen, George L. Farnsworth and A. E. Butters. Rights to 1,650 acres of coal land have been obtained. About one hundred men will be employed at the opening of the mine. The third vein is reached at a depth of 525 feet. Rutland is served by the Illinois Central and the Sante Fe railroads and two hard roads as well.

## Obituary

Charles A. Wall, of St. Louis, Mo., formerly owner and operator of mines at Du Quoin, Sparta and Murphysboro, Ill., died at his home, July 23. At the time of the death he was chairman of the board of the Devoy & Kuhn Coal & Coke Co.

Joseph A. Huddleston, head of the Excelsior Coal Co., operating at Excelsior, W. Va., succumbed to an attack of heart failure at his home on Dry Fork, July 21. He was well known in southern West Virginia, as he had actively participated in civic affairs and aided in developing Welch and the territory of which it is the center.

Michael A. Snyder, 86 years old, retired coal man of Louisville and formerly head of the old Snyder & Himpell Coal Co., which dissolved some years ago, died on July 16, following a long illness. Mr. Snyder was a native of Germany, going to Louisville as a young man and starting in the coal trade. A widow and two daughters survive. He was a veteran of the Civil War.

## Traffic News

### B. & O. Seeks Federal Injunction Against Indiana Rate Cut

Alleging that reduced rates on coal established by the Indiana Public Service Commission in an order last February are unreasonable and unjustly discriminatory and in violation of the act of Congress to regulate commerce, the Baltimore & Ohio R.R. and more than twenty others have filed suit against the commission in federal court in Indianapolis seeking an injunction restraining the commission from enforcing the order. The railroad companies also seek an order restraining the commission from enforcing or attempting to enforce any fines or penalties for failure to comply with the commission's orders.

### Indiana Wants Lower Rates on 56 Central West Roads

Reductions and adjustments in freight rates on coal from Ohio, Kentucky and West Virginia mines have been asked in a complaint filed by the Indiana State Chamber of Commerce with the Interstate Commerce Commission against fifty-six railroads in central Western states. The complaint seeks to adjust rates from the mines to practically all Indiana points. The railroads named as defendants serve what is known as the Central Freight Association territory. It alleges that rates now in effect do not take into consideration competitive conditions and are discriminatory compared with rates in surrounding territory.

Cuts in Eastern coal rates were obtained for Indiana consumers last year and early this year, and the action just taken seeks to harmonize central Western rates. The new action alleges that present coal rates from the three states named were not made in accord with the conditions which exist in competitive fields, and do not take into proper consideration mileage tables and distances. An adjustment with various reductions for various sections of the state is sought.

### Hears Evidences in Tell City and Cannelton Rate Case

Arthur Mackley, Interstate Commerce Commission examiner, has just heard evidence in the Tell City and Cannelton coal-rate case against the Southern Ry. The case was filed on behalf of the Cannelton Sewer Pipe Co., of Cannelton, Ind., the United States Brick Co., of Tell City, Ind., and others. The petition seeks an order from the commission to give the Indiana Public Service Commission authority to pass on certain reduced rates. W. W. Webb, traffic manager of the sewer pipe company, testified regarding rates. He said the petitioners are seeking to have coal rates of \$1.12 a ton from Oakland City, Winslow and Francis County, Ind., and 98c. from Boonville and Chandler. The companies also are seeking reparations

amounting to about \$8,000 on rates which were fixed by the commission and defeated by an injunction issued by Judge A. B. Anderson in federal court in Indianapolis. The injunction order prevented any interference with certain rates which were in effect during the period from March 15, 1921, to April 7, 1922.

### Rates Cut to East St. Louis From Southern Illinois

Rates on coal from the "inner group" mines of southern Illinois to East St. Louis, Ill., have been ordered reduced from 90c. to 71c. and from 90c. to 80c. by the Public Service Commission of Illinois. The commission has divided the mines in the group into two zones. The 71c. rate will apply to shipments from mines within thirty miles of East St. Louis and the 80c. rate to inner group mines beyond the thirty-mile limit. There are approximately 135 mines in the inner groups and 80 per cent of the bituminous coal used in St. Louis and East St. Louis and environs comes from these mines. The mines are served by twenty railroads.

### Cut in Indiana Rates Postponed

The Indiana Public Service Commission has postponed from July 25 to Aug. 1, the date for the taking effect of the new low intrastate coal rates. The postponement was made upon the suggestion last week of Judge Samuel Alschuler, in the federal court at Hammond, Ind., in whose court the railroad companies asked an injunction against the order. Judge Alschuler suggested that if the date were postponed, he would not have to issue a restraining order to be in effect until a hearing could be held before three judges. That hearing is now in progress.

## Coming Meetings

**Western Canada Fuel Association.** Convention Aug. 5 and 6, 1924, Brandon, Manitoba, Can. Secretary, W. H. Morrison, Winnipeg, Man., Can.

**Rocky Mountain Coal Mining Institute.** Summer meeting, Aug. 7-9, Rock Springs, Wyo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

**New York State Coal Merchants Association, Inc.,** 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

**American Chemical Society.** Fall convention Sept. 8-11, 1924, at Ithaca, N. Y. Secretary Gas and Fuel Section, O. O. Malleis, the Koppers Co., Pittsburgh, Pa.

**Oklahoma Coal Operators' Association.** Annual meeting Sept. 11, 1924, McAlester, Okla. Secretary, A. C. Casey, McAlester, Okla.

**Association of Iron and Steel Electrical Engineers.** Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Electric Grinding Outfit For Heavy Shop Work

The Cincinnati Electrical Tool Co., Cincinnati, has added to its line a 5-hp. heavy-duty floor grinder, which has been designed for use in shops where heavy grinding is required.

The motor is mounted on ball bearings and is fully inclosed to prevent emery dust and dirt from getting into the bearings and windings. The ball bearings are locked to the shaft in a manner intended to provide for end thrust and also to eliminate wear and friction. The machine will carry wheels

Heavy Electrically Driven Grinder

up to 18-in. diameter and having 3-in. face. The wheel guards are of the exhaust type complying with safety standards and are adjustable for wear of wheels. Removable covers are bolted to the guards completely inclosing the sides of the wheels, flanges and nuts to assure safety to the operator at all times.

The starting switch is of the magnetic type, push-button control and is mounted accessibly on a separate panel within the column. The grinder is available for alternating current 220 and 440 volts, 25 to 60 cycles, two or three phase.

### Gasoline-Driven Compressor For Small Open-Air Jobs

It is amazing what a multitude of jobs about the mine can be performed more efficiently by the use of compressed air than by any other means. In order to meet the need for a small self-contained compressor plant capable of furnishing enough air for many of the operations about mine surface works the Ingersoll-Rand Co. has recently placed upon the market the outfit shown in the accompanying illustration.

Essentially this outfit consists of a four-cylinder, four-cycle, tractor-type gasoline engine direct-connected to a 4½x4 in. duplex air compressor having a rated capacity of 60 cu.ft. of free air per minute. Both engine and com-

### Air Compressor Plant on Wheels

For drilling in strip pits, for blowing out blast holes for operating paint sprays or sand blasts and for other surface uses for compressed air this air-compressor plant may prove handy. The air is compressed near the work and so the line loss from leakage and friction is small.

pressor are water-cooled, a fan, pump and sectionalized radiator being provided to prevent the water boiling away. Furthermore the compressor is equipped with a regulator and the engine with a control which reduces its speed during unloaded periods.

This machine has sufficient capacity to operate a jackhammer or do odd painting or cleaning jobs—operate

paint sprays or sand blasts. It will furnish air for a trench digger, two back-fill tampers, two calking or chipping hammers or one riveting hammer. It may be mounted as shown on a wagon with steel wheels and axles or upon one with wooden artillery wheels with solid rubber tires, on an automobile truck or on plain skids as the customer may desire.

### Tractor Crane That Crawls Around Sharp Corners

In the operation of the 10-ton crawling tractor shovel manufactured by the Industrial Works, Bay City, Mich., the traveling, slewing and hoisting motions are independently controlled. These motions may be utilized in a variety of combinations which are said to result in a greatly increased speed and efficiency of operation. For instance in bucket work the hoisting and slewing motions may be combined for operation at high speed and when traveling the boom may be swung in any direction to clear obstructions. By a double friction clutch and a train of bevel and spur gears the truck can be slewed in either direction without reversing the engine.

A slewing brake holds the boom securely in any position, even with a suspended load. When operating on uneven ground this brake eliminates any possibility of sudden rotation with its

usual disastrous results. The vertical slewing shaft is located accessibly at the front of the crane close to the base of the boom, and as the power is transmitted at this point no great slewing stress is carried through the revolving frame.

The new tractor crane is built for either steam, electric or gasoline power. The steam unit has two horizontal double-acting cylinders of 6-in. diameter and 8-in. stroke. The crane is extremely versatile, operating with clamshell or dragline bucket, hook and block or grapple. It is readily convertible into a shovel or pile driver, making it a general utility unit.

### Picker Segregates Slate by Selecting the Thin Pieces

Many have been the machines and mechanical devices developed during past years to pick slate from coal. Many if not most of these machines seek to utilize either the difference in

the shape of the coal and slate particles or their differing coefficients of friction. One large class of slate pickers takes advantage of the fact that slate is normally thin and flat and consequently will pass through a narrow opening while coal being of more cubical shape will not.

One of the latest machines of this type intended to be attached to an ordinary shaking screen is known as the Mason flat slates picker after its inventor Fred H. Mason, 1634 Brown Ave., Scranton, Pa. This machine, shown in the accompanying illustration, is so designed as to "clear itself," that is, free itself from slate particles too thick to pass through its openings.

Essentially this machine, consists of a stepped series of transverse plates fastened in position between side plates and forming the bed or bottom of the device over which the mixture of coal

Elevation

Section

Elevation and Section of New Picker

and slate slides. Between the edges of the plates and extending entirely across the shaker, rods are placed, so mounted that they may reciprocate back and forth in short slots cut in the side plates. Outside the side plates these rods are supported by, and move under the action of, springs, the tension of which tends to keep the rods always at the forward ends of the slots. In other words a rearward movement of the rods in the slots is opposed by the action of the springs.

In operation the coal being too bulky to pass through the opening between a rod and the plate below it moves on over successive plates and out of the device. Slate, on the other hand, being thin and flat moves backward through the space between the rod and plate and falls out of the machine. Any piece too thick to pass readily through the opening provided is assisted by the rod movement the amplitude of which is comparatively small, amounting to only about  $\frac{3}{8}$  in. in the case of chestnut coal, that adapted to other sizes being proportional.

In actual use this machine has shown excellent results. A sample of the material picked from the coal by it was found to be of the following composition:

Total weight of sample.....	92 oz.
Slate in sample .....	74 oz.
Bone in sample .....	9 oz.
Flat coal in sample .....	9 oz.
Reduced to percentages these results are:	
Slate .....	80 $\frac{4}{9}$ per cent
Bone .....	9 $\frac{7}{9}$ per cent
Flat coal .....	9 $\frac{7}{9}$ per cent

These results speak for themselves and need no comment. It should be borne in mind, also, in considering them that they were obtained with an extremely simple device attached directly to a reciprocating sizing screen.

Traveling, Hoisting and Slewing Motions of This Crane Are Independent of Each Other

The stability of the shovel without any aid from track fastenings or outside jacks, without which the true railroad crane can

do but little, will attract attention. The advantage of the caterpillar lies not only in greater mobility but in stability also.

## Consumer Obligation

THE care-free consumer, as usual, is found to be the cause of high prices and coal shortages in the report of the coal-storage committee of the American Engineering Council. He lives through the summer like the grasshopper of the fable and laughs at the ants that prepare for the winter. The consumer by his numbers, his ubiquity and vociferousness has put the blame for shortage on the producer. The mine owner has been tried in the court of public opinion by a jury not one man of whom was unprejudiced.

The farmer must plow in the spring for the fall harvest, but the consumer must be served when, where and how he elects. Being so many, being spread in every state, the consumer's voice controls legislators and newspapers, so that what he wills he should have. Is it not written "The customer is always right" and that "The voice of the people is the voice of God"?

## Who Is Sinning Now?

THE SANCTITY of contract between employer and employee ought to be respected by both parties equally. For this reason it is not possible for this paper to support the course of action followed by certain operators in Oklahoma who, as members of their operators' association, were definitely committed to the Jacksonville agreement, but who, in order to evade the obligation of the contract, withdrew from their association and opened their mines on a non-union basis with wages at the 1917 level. This withdrawal is an evasion and ought not to have been attempted.

These operators must have known in May, when their association signed the agreement, that the market situation would be about what it is now. The time for them to have foreseen the impossibility of operating under the Jacksonville agreement and to have withdrawn from their association was before they became parties to the contract. The thing for them to do now is rejoin their association and add to it all the strength possible. Then the futility of the Jacksonville agreement should be proven to the union miners of that district by the association so convincingly that adjustments be made, President Lewis' never-give-in ultimatum to the contrary notwithstanding. Hungry men, beaten by the operation of the irrevocable laws of supply and demand, cannot be blind for long in Oklahoma any more than in western Kentucky where unionism is a losing cause.

Let contracts be sacred, come what may.

## Water as an Aid to Explosions

WATER helps to prevent explosions by keeping down the dust, and it may serve to extinguish explosions when not in the form of steam or vapor. It tends doubtless to cool the temperature of the blast when in the latter form, for water has a great capacity

for heat or as it may be expressed, a high specific heat.

But Mr. Ashworth in his discussion is correct in saying that steam aids combustion of methane by assisting in the chemical change which is known as combustion. Those who believe that saturated air will prevent explosions are entirely at fault. It tends, instead, to aid them. The value of supersaturated air is that it drops moisture and so dampens down the dust and tends to keep it from rising and also protects the workings from explosions in the same way as any other water.

Such supersaturation of the air must be of long duration or the water deposited will be of insufficient quantity. Saturated air is of value because it prevents the drying of the mine when it contains moisture. But it must be always saturated. It will not retard but rather aid explosions if saturated only at the time of the explosion.

As has been repeatedly stated, 30 per cent of water is necessary for immunity. The dust must be so wet that water can be squeezed out of it by pressure in the hand. It is difficult, almost impossible, to assure oneself that the dust is thus wet. Consequently rock dusting is preferable, so much so that to rely on water is suicidal. But water has its place also, as Mr. Walls says in the discussion department of this week. It is needed where mining machines are used, when coal is broken by explosives at the face and where cars are dumped underground, not only for the good it does at those places but also because it prevents the dust from being carried into other areas, especially into those sections of the mine where rock dusting is extremely difficult because not being laid with track the machines for rock dusting cannot reach them.

## Gas or Coal?

SO LONG HAVE we been rebuked by all and sundry about our wickedly irregular operation at coal mines that W. S. Blauvelt's article in this issue will be found exceptionally interesting. He assumes a 40 per cent capacity operation for the gas industry equivalent to 146 days in the year. Of course, the works run throughout the year but they have, except at steel plants, only that percentage operation as far as capacity is concerned. That is larger than the figure Mr. Orrock mentioned in his statement at the World's Power Conference. He put the figure at 30 to 35 per cent. It shows how grievously inefficient gas plants are and must be. No one is to blame. When inefficiency of this kind appears it is not considered to be objectionable and discreditable to the business in which it is discovered—unless it is the coal industry.

Mr. Blauvelt says that the interest maintenance depreciation and taxes cost of distribution are 22½ cents and the value of the gas 35 cents per thousand cubic feet. Adding to the distribution costs the costs of pumping and of gas losses the total is 27½ cents. That is 80 per cent of the value of the gas distributed. This

is a huge distribution cost, by no means discreditable to the gas industry, but one that the public would be prone to think heinous on the part of a coal company despite the long distances over which the coal might happen to be transported.

We begin to see why gas is made in the home in greater volume than at the gas works. However, we are disposed to believe and have been told that gas can be produced at far lower costs and is being so produced in Germany and we believe at one place in this country. We are informed that the pressures of distribution are too low and might be raised. It seems quite likely that even at higher pressures the losses might be made less. There are difficulties connected with both those suggestions. The same state and municipal authorities that are the Nemesis of the gas industry might interfere with either or both these means of cheapening gas. We wonder however whether an aggressive campaign of publicity might not aid the gas companies to get some relief from oppressive legislation and ordinances, provided, of course, the new methods of making gas, the new gas mixtures, and the higher pressures in distributing it are desirable.

But to revert to the cost of distribution. The pipes are like the salesgirl at the store. They wait on the consumer, ready to serve, but the consumer is slow to buy. The salesgirl could sell ten times as much as she does in the course of the day, but the public is not ready and willing to make purchases. Payment must be made for her loss of time, and similarly the public must pay for idle gas lines. If people will buy gas only when they want to cook a meal or heat an iron, the pipes must be idle for hours at a stretch. The public must pay for that.

We have only just commenced to study losses. Coal has received an attention from the economists that in time must be expanded to take in all industries. When that inquiry is made, we have no doubt that coal will be vindicated. The searchlight has been directed so persistently on coal that we are blinded to all else. The question is whether knowing the truth we can do more than deplore it. Each industry has known it for years. Every industrialist has tried to eradicate waste from his own operation. When those who do not understand the industry start out to reform it, will they get any further than hopes, vain hopes? We expect that reform will be internal rather than external. The public more often hinders than helps and almost never reforms.

Meantime let the coal yard flourish!

### Trip-Gathering Problems

THE PRACTICE described by Anthony Shacikoski in this week's "Problems in Underground Management" as the normal way of handling locomotive trips is, as he says, not conducive to large tonnage from the miner or maximum efficiency in locomotive operation. But is it indeed the normal way? In some mines the headings are kept well in advance of the working places. When that is done the locomotive can push the loads beyond the live rooms and bring the empties up behind it. As soon as these empties have been switched into the rooms the locomotive can bring out its train of loads, the time being occupied by the trip rider and motorman in the coupling of cars. Of course, the butt headings cannot be made indefinitely long, for the longer they get the more time is lost.

When they reach the property line, the outcrop or a length at which it is desirable to terminate them, the difficulties Mr. Shacikoski describes come into being. Then it is customary to put the empties ahead of the locomotive and with them forming a composite trip of loads and empties push the loads back. That duly done, all the empties as far as possible are stowed in working rooms, two or even more being run into rooms near the face so that they may be left near the end of the roadway and, in consequence, reasonably accessible to the inbye rooms.

This, however, though a common is not a safe practice, the pushing of a long trip of empties and loads in the presence of switches being quite liable to cause derailments. Furthermore, it frequently overtaxes the locomotive, especially if the grades are heavy and the power deficient, as is too often the case where the heading is long and both feed and rail return are none too effective owing to the distance that the current must travel. In some mines the working rooms are at all times near the end of the room entry and in that case, which is quite frequent, the empties almost always are pushed by the locomotive.

But perhaps Mr. Shacikoski is thinking of the practice in mines with thick coal where butt entries are usually short and cut off at frequent intervals by face headings, forming what are known as panels. There his method is not only convenient for the men and helpful to the locomotive but also safer as far as haulage is concerned than those described in the foregoing remarks.

However, it must be remembered that it presupposes the existence of an inbye face heading which may be actually only in contemplation. It often is not in existence but only laid off on the map. Development even in mines with thick coal is frequently thus far advanced, and sometimes it does not pay to advance it to such a degree.

Excessive development is often a cause in itself of low locomotive efficiency, for a locomotive in that case has to travel long distances between the ends of headings, gathering in the meantime only a small coal tonnage from the heading men. It is also a cause of low ventilation efficiency, for the current has to travel a long way merely for the heading men. A small current will serve if there is no gas, but if there is, a large current out of all proportion to the men engaged may be needed and the water gage must be high in consequence.

Granted, however, that there is such development the connections described will, in the absence of doors, make ventilation impossible, and doors are to be avoided especially where the coupling of trips is likely to compel them to be kept open for long periods. In some cases the grades might permit the actual coupling to be done beyond the door but the uncoupling of the empties even if done on a moving trip would make it necessary to move so slowly that the door would be open too long.

Oftentimes, even usually, the cars cannot be uncoupled while moving because, the grade being against the direction of travel, the couplings are stretched. Should the barrier pillar and chain pillar be thick the assembling might be done satisfactorily short of the door. Then the only trouble with the plan will be to regulate the air travel through the room entry so that the entries above will not be deprived of air. Where the mine is large that problem will be perplexing.

# English Washery Cleans Coal Before Sizing

Slack Today Must Be Clean to Be Salable—Compressed Air More Efficient in Action Than Plunger—Fines Carefully Drained and Mixed with Larger Sizes

By C. H. S. TUPHOLME  
London, England

IN RECENT years British coal-mine operators have realized that slack coal could be disposed of readily only if reasonably clean and free from dirt. This is true whether the fuel is placed on the regular market or used in coke ovens. Several methods have been tried for cleaning the raw slack as brought from the mines, but the system that has given the best results and has shown itself to be the cheapest to operate is that in which the slack is washed by immersion in specially constructed tanks containing water, which is subjected to pulsations of short duration sufficient to cause the slack to be thrown momentarily into suspension. Because of its lower specific gravity, the slack coal is held in suspension for a longer period than the intermingled dirt, and is thus carried forward in the current of washing water and finally separated from the impurities.

The usual method of carrying out this process is by means of a tank equipped with a division plate as shown in Fig. 1. The raw slack passes through the tank over a fixed sieve or perforated plate on one side of the central partition. On the opposite side of this plate generally is an arrangement of plungers or bashes, operated by eccentrics. These exert pressure on the water on the downward stroke, forcing it up through the screen and raw coal on the other side. The separation of dirt from the coal occurs during the upward stroke of the plunger.

A washer of a somewhat different type, that has proved highly successful in Great Britain, is the Baum. In this machine the plungers are replaced by compressed air controlled by piston valves. Air at a pressure of about 2 lb. gage is admitted to the washing tank through these valves, which retain the air under pressure on the downward and release it on the upward stroke. The bed of coal is forced upward when the valve ports are closed,

Fig. 2—Longitudinal Section of Baum Jig

In this machine the plunger of the ordinary jig is replaced by air under pressure. This is alternately admitted to, and released from, one side of the machine, causing water to surge upward through the screen and then settle back easily.

and separation of clean coal from the dirt occurs during the downward movement of the bed when the ports open and the air is released.

## COMPRESSED AIR ACTING DOWN FORCES WATER UP

A recent installation of this kind, shown in the accompanying illustrations is that at the Normanton Colliery of Pope & Pearson, Ltd.. It was built by Simon-Carves, Ltd., and is intended to treat 125 tons of coal per hour. In this plant the coal to be washed is brought in in railroad cars and discharged into an underground feed hopper from whence it is elevated into the building. The coal leaving the top of the elevator is flushed by water into the first washer box.

This washer box has a semicircular bottom, being divided longitudinally into two portions. One side is fitted with horizontal screens over which the coal is carried by the flow of water. The other side is provided with a set of air valves that allow puffs of compressed air to act on the surface of the water below. The pulsating movement thus set up brings the coal to the top of the bed, the dirt sinking to the screens, as explained before. Any small dirt falling through the sieves is taken to either end of the washer box by means of screw conveyors at its bottom.

Fig. 2 is a longitudinal and Fig. 3 a transverse section

Fig. 1—Cross-Section of Simple Jig

This shows the division plate slightly off-center with the fixed screen on one side and the plunger or piston on the other. Reciprocation of the piston causes an upward and downward movement of the water through the screen and bed of material upon it. This causes the heavier particles to seek the screen and the lighter coal to rise to the top of the bed.

Fig. 3—Transverse Section of Baum Washer

The illustration shows clearly the air chamber and the air control valves operated from eccentrics on an overhead shaft. Inasmuch as air is perfectly elastic and as both upward and downward surges of the water through the screen are cushioned thereby, this washer is "easy" on the coal that it treats, and degradation within the machine is small.

of a four-valve Baum washer box. A single box of this type is capable of handling raw slack passing through a 3½-in. mesh at a capacity of about 75 tons per hour. For capacities up to 150 tons per hour an additional box is provided in which the fine coal is rewashed.

The operation of this machine is as follows: Compressed air enters the valves at *C* and passes directly through to the air chamber when the piston covers the valve ports. When the piston is at the opposite end of the stroke the ports are open, thus allowing the air to escape to the atmosphere. The continuous operation of the valve gives the required movement to the water in the washing chamber. The raw coal enters at *F* and is deposited on the screen *K* in the first section of the box *E*. The heavy dirt collecting on the screen is taken away continuously through the adjustable sluice gate *G*, passing down the chute *H* into the dirt elevator *J* by which it is elevated and drained before being discharged.

Coal, with any middlings product or light dirt, overflows into the second part of the washer box *M*. The dirt collects on the screen *R* and is passed continuously at a suitable rate through the adjustable sluice gate *O*, down the passage *P* and into the buckets of the dirt elevator *Q*, where it is treated exactly like that in the elevator *J*. The finest dirt collecting on the screens *K* and *R* passes through the perforations and settles to the bottom of the washer box. Thence it is conveyed by the worms *L* and *S* to the elevators *J* and *Q*.

Washed coal from the second compartment *M* over-

flows from the outlet *N* and passes to the classifying screens or to bins as required.

Experience has shown that the advantages of using compressed air to produce the pulsations in a washer, as compared with the ordinary direct-acting piston or bash, lies in the fact that the air acts as a cushion during the return stroke, and so eliminates all suction. The object of the transverse division of the washer by plates is to insure the proper pulsation of the water. Gates or sluices are fixed at either end of the screens and at the front end the raw coal passes over the gate into the box while the heavy dirt passes immediately under the gate into the dirt elevator. At the other end the washed coal passes over the gate while the remainder of the dirt is drawn out into the second elevator. These gates can be regulated to a nicety, thus obtaining an efficient separation. Once the machine has been adjusted for a particular kind of coal consistent results are obtained.

The washed coal flows with the water from the washer box into a set of large, revolving, classifying screens provided with mantles to size the coal into what in British parlance are known as nuts, beans, peas and fines. The three larger sizes pass over drain sieves where they are sprayed, and thence down spiral chutes into storage bins.

Should the raw slack contain a large percentage of interstratified rock, this material can be extracted as a separate product and collected in the dirt elevator *Q*. Thence it can, if necessary, be passed through a crusher, and back to the washer box for retreatment.

Wash water enters the box through the valves *T*, the supply of both water and air in each part of the box being regulated separately by the different valves shown.

Fig. 4—Section of Water-Clarification Tank

The arrangement of this tank and the various pipes leading to and from it is such that, although its action is continuous, clear water is taken off at the top and sludge at the bottom. This latter is dewatered, mixed with the larger material and sold.

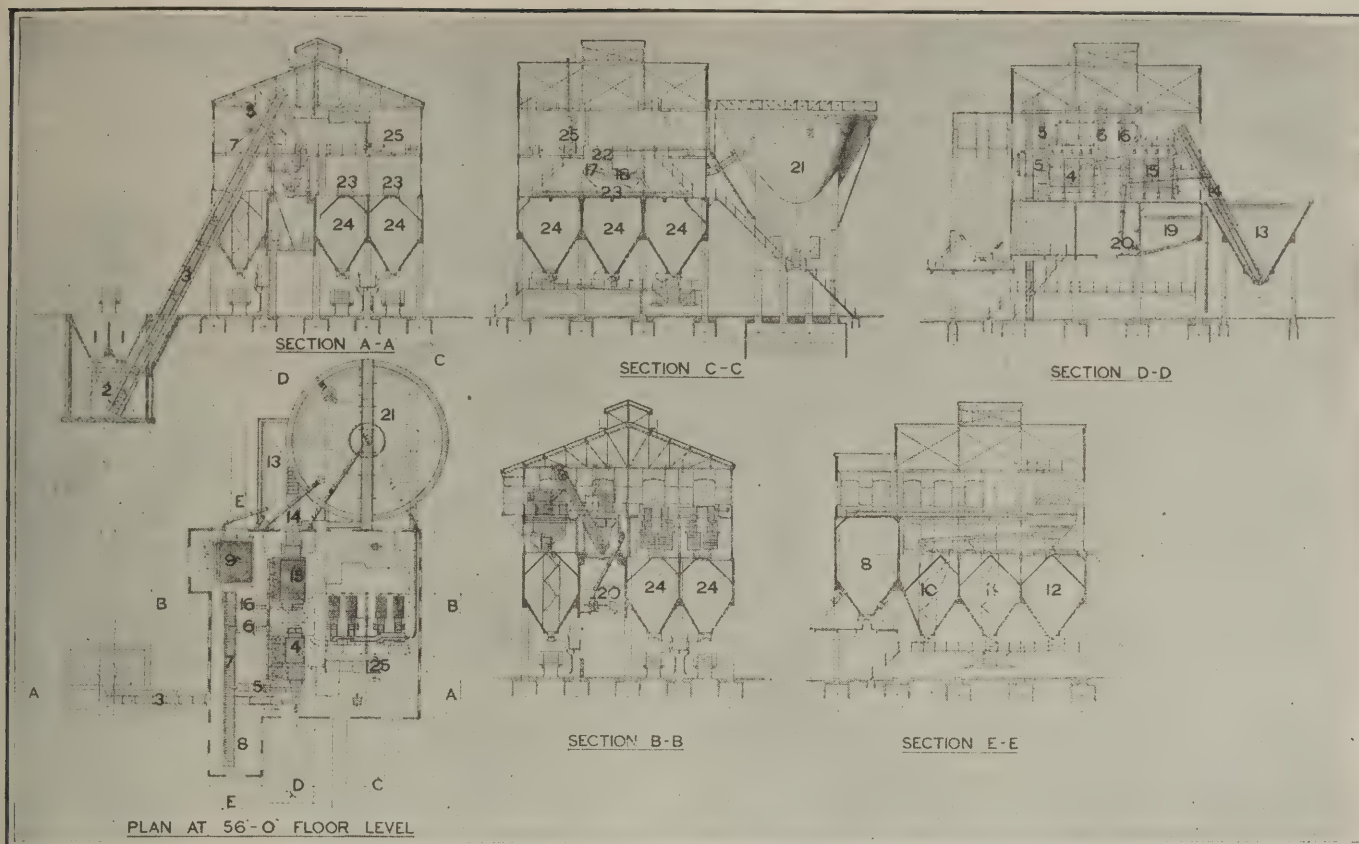

Fig. 5—Various Sections of a Large Capacity Washery

This installation is intended to prepare coal of  $3\frac{1}{2}$  in. and smaller at the rate of 150 tons per hour. After washing and screening the larger sizes are carefully lowered down spiral chutes into the storage bins. The finer sizes, naturally, are not treated so gently.

Water leaving the box at the outlet end together with the washed coal can be drained off and collected in the settling tank.

In this process it is found that an even pressure is obtained along the whole length of the washer. As on the return stroke the air acts as a cushion, the downward movement of the bed is retarded, and the maximum time is allowed the various materials for separation according to their respective specific gravities.

Wear and tear on the various parts of the machine is small, the valve pistons operating at a speed of only 40 to 50 strokes per minute. The absence of direct-acting plungers does away with the liability to breakdown as no function of the air pistons is sufficiently strenuous to make this contingency possible. As a matter of fact, wear on the pistons is negligible so long as they are kept well lubricated. Power required for operating the valves is therefore practically nil.

It is possible to wash slack smaller than  $3\frac{1}{2}$  in. without initial classification into various sizes, thus eliminating dry screens. These are in many cases costly in maintenance and supervision, and also, are not always efficient.

It will be understood that the principle of classifying after washing prevents degradation of the various sizes produced. This is an inherent attribute of the Baum washer; another advantage is the avoidance of dust production.

The fines together with the water pass from the revolving screens into a "smudge" sump. Here the surplus water overflows into a collecting sump and the fines are removed by an elevator to a rewashing box. This machine is of similar construction to the first but is provided with a wider bed and the pulsations are much

more gentle so as to separate fine dirt and coal. The washed fines after leaving this box flow with the water to the fine coal and slurry dewatering plant, which is simple in action and takes up little space.

In this type of washer a feldspar bed is not required. All the bed necessary is provided continuously by the dirt extracted from the raw slack.

The coal becomes cleaner as it passes along the first section of the box, the capacity thus being greatly increased. In other words, more can be accomplished in a small area than a large area where the coal and dirt are separated only at the outlet end of the washer.

The lighter products from the first section are again treated in the second section where the last traces of dirt are extracted. The complete separation of extraneous material is thus performed in one continuous operation. Large dirt particles are collected along with the finer material from each section in one elevator. The larger dirt thus acts as a filter for the smaller stuff. In this manner all the dirt is handled mechanically and is drained to a condition where it may be disposed of without further handling. The washing boxes themselves are constructed deep enough to allow the small dirt to settle without the possibility of its being carried away with the current of water and getting mixed with the coal.

#### EFFICIENT SEPARATION OF SLURRY

Temporary stoppages of this machine do not alter the quality of its products, as an air relief valve can be opened immediately stopping the action of the washer. Thus, there is no possibility of the whole bed being washed out of the box through the dirt gates, as is sometimes the case when plunger jigs are used.

The elevated conical tank (see Fig. 4) is the main water reservoir for the washery. It is here that the settlement of the slurry and the clarification of the dirty water takes place. This tank is located at such an elevation that the clean water can flow by gravity through the pipe *B* to the washer boxes. After doing its work in the washers, and finally being collected in a sump, it is pumped back to the tank through the return pipe *C*. The outlet of this pipe is surrounded by a steel curtain *D*, perforated at its lower edge. This guides the suspended material downward without disturbing or contaminating the clean upper layers of water from which the washing water is drawn. The velocity of the incoming water quietly decreases, thus allowing the fine solids to settle gradually to the bottom of the tank.

An outlet *E* is arranged at the bottom of the tank, provided with a cock *F*, so that all fine material or slurry can conveniently be allowed to pass by gravity through the pipe *G* back to the washery to be mixed with the fine coal. An overflow pipe *H* is provided to insure a constant head while the fresh water to replace that lost in the washed coal enters through the pipe *J*. An auxiliary water pipe *K* connects with the pipe *G* to regulate the consistency of the slurry. One circulating pipe serves the entire installation.

Where it is necessary to classify the washed coal for "sales" the latest plant is arranged for delivery of the nuts and beans by gravity from the screens direct to the bins, thus avoiding the introduction of water for conveying the larger material after it has been classified. The fine coal is delivered from the washer box or classifying screens, as the case may be, to shaker screens. The slurry recovered from the settling tank is also delivered to these screens along with the fine coal. In addition to being drained this material is intimately mixed with the fine coal, so that the smudge or fines has a good appearance when offered for sale.

In many cases the moisture is reduced sufficiently to enable the coal to be passed directly into a small bin of, say, 40 tons capacity, and from there to railroad cars. Where it is necessary to reduce the moisture still fur-

ther for coking purposes the fine coal and slurry from the shaker screens can be delivered into drainage and storage bins. If a large storage is not required the mixture of fine coal and slurry can be delivered to a draining conveyor. The drainage water from the shaker screens is collected and sent back to the conical settling tank.

The washery at Normanton contains inclined drainage sieves taking the surplus water out of the fines, as well as shaking screens that agitate the fine coal and slurry together while draining them. The fines after travelling down the inclined sieves, which are fitted with brass wires of wedge-shaped section with fine slits between them, fall onto the shakers which are fitted with similar screens. As the fine coal is moved along these screens by the vibration, the slurry which has settled from the washery water flows by gravity to an upper set of inclined sieves. From these it falls on top of the fines which act as a filter bed and allow the slurry to be dewatered without getting back to the circulation water.

The fine coal and slurry leave the vibrating screens in a well-drained condition and are distributed by scraper conveyors to a set of three bins. These are equipped with perforated grids at their bottoms and their outlets are provided with special drip trays. The fine coal and slurry being uniformly mixed continue to drain in these bins until drawn off to cars.

The water-collecting sump is emptied by a centrifugal pump that discharges to the conical settling tank. The slurry settles to the bottom, passes through a mouth-piece and is transferred by a pipe to the drainage screens, the head of water in the tank forcing the slurry up to these sieves continuously. Thus there is no pumping or mechanical handling of the slurry, and in consequence the water in the tank is not disturbed, the settlement of the slimes being uniformly maintained.

The entire plant is operated electrically. Great care has been taken to provide easy access to all moving parts for inspection and lubrication.

The lower portion of the building at Normanton,

FIG. 6  
Normanton  
Washery

In England, as in this country, coal preparation has become a science. That coal washing pays may be judged from the type of washery shown in this illustration. All parts of the building coming in direct contact with water or wet coal are of concrete, the rest of the structure being a steel framework filled in with brick paneling. Though such buildings are higher in first cost than the wooden structures of similar nature frequently built in this country, as they depreciate slowly the greater cost is justified.

FIG. 7

**Washery Interior**

This reveals with unmistakable clearness the extreme neatness of the interior of the Normanton washery. Few washeries in the United States can compare with it in this respect. One air-actuated washing unit can be seen in the foreground with its air valves and eccentrics. Another unit appears in the rear of the illustration. The air main can be seen at the back of the nearer washing unit. The lower parts of the washing chamber are hidden by water. This view, though not as broad in scope as section D-D in Fig. 5, is seen from about the same point. The various parts can be recognized by a glance at the horizontal section in the same figure.

including the storage bin, is constructed of reinforced concrete, and the settling tank and feed hopper are of this material throughout. The upper part of the main building has a steel framework which is filled in with brick panelling. The entire structure is covered by a reinforced-concrete roof. It is interesting to note, in passing, that the buildings comprising this plant are located upon made ground, particular care being necessary with the foundations. Both the washery building and the settling tank are supported on reinforced-concrete rafts extending under their whole area.

An earlier installation of the Baum washer intended to treat 150 tons per hour, is shown diagrammatically in Fig. 5. This is located at the Penallta Colliery of the Powell Duffryn Steam Coal Co., Ltd. The raw coal is delivered to the underground hopper (1) from the bottom of which it is withdrawn at a uniform rate by the chutes and revolving feed tables, (2). The coal is thus delivered to the boot of the elevator, (3). This elevator carries the whole of the raw product direct to the washer boxes, (4). The heavier dirt is drained in the elevator (5), and the lighter dirt in the elevator (6), both of which deliver to the scraper conveyor (7), which carries this material to the bin (8).

The washed coal is then separated into four sizes in the revolving screens (9). The nuts and beans are passed over drain sieves into their respective bins (10) and (11), which are fitted with spiral chutes. The peas pass direct into the bin (12). The fine coal collects with the wash water in the smudge sump (13) from whence it is removed by the smudge elevator (14) to the rewasher box (15). The dirt from this jig is lifted by the elevator (16) to the scraping conveyor (7).

The washed fine coal flows to the drain sieves (17), and from there to the shaker screens (18). The water

and slurry drained from the coal pass into the smudge sump (13), from whence the water overflows to the pump sump (19). The centrifugal pump (20) lifts the water from this sump to the settling tank (21). The slurry from the settling tank returns by gravity to the washery, and after passing over the dewatering screens (22), is thoroughly drained and mixed with the fine coal on the shaker screens (18). The combined products pass to the scraper conveyor (23) which distributes the washed coal to the fine-coal bins (24). The washed coal is taken away in railroad cars, the larger sizes being loaded by means of special chutes. Dirt is removed from its bin in mine cars. Compressed air for the washer boxes is produced by the blower (25). The entire plant is operated by three electric motors.

### North Carolina Mines Started in 1830

Across the State of North Carolina and parallel to its east and western boundaries runs what appears on the map as a narrow scar. It is the Triassic formation. In the center of this strip was an old plantation owned by Peter Evans and located in the great northward bend of the Deep River, including the village now known as Cumnock and the area known as Egypt. Mining started in 1830. In 1852 the Egypt shaft was sunk which reached the Cumnock coal bed at 430 ft. After the Civil War the name of the company was changed to "The Egypt Co." During that struggle it shipped coal part by railroad and part by barge to Wilmington, the coal being used extensively by blockade runners. The mine was closed in 1870 and remained flooded till 1888. In 1902 it closed down, having a bad reputation for gas explosions. Since 1922 the mine has been actively developed by the Erskine Ramsay Coal Co.

# Why Gas Rarely Replaces Coal for House Heating

Municipal Standards Prevent Service at Minimum Cost — Small Consumer Does Not Pay Reasonable Price for Investment He Makes Necessary — Gas Company Has to Lay Distributing Pipes, Whereas Coal Goes Over Public Highway

BY WARREN S. BLAUVELT

President, Vigo Mining Co.,  
Terre Haute, Ind.

**M**ANUFACTURED gas, in competition with anthracite and bituminous coal, for heating houses, is generally handicapped in two ways, and without exception is heavily handicapped in a third way.

One of these handicaps is the prevalence of city or state gas-quality standards which do not permit the distribution in each locality of the particular kind of gas which could be manufactured and distributed so as to give the maximum service at a minimum expense.

Another handicap is the general prevalence of inequitable gas rates. Commonly the consumer whose maximum hourly consumption is excessive compared with his average monthly bill, pays less than the cost of his service, whereas the consumer whose maximum hourly consumption is relatively small compared with his average monthly bills, pays far more than the cost of his service. The third and most serious handicap on gas consumption for house heating will be developed in the following discussion.

Gas with a heating power of 400 B.t.u. per cubic foot can be manufactured on a large scale, from coal costing \$5 per ton delivered at the works, and sold profitably, *at the works*, for an average price of 35c. per thousand cubic feet, if the average rate of operation for the entire year approximates 40 per cent of the rated plant capacity. As the heating efficiency of gas appliances greatly exceeds that of coal-burning apparatus, and as gas consumption is automatically controlled to meet instantly varying requirements, in actual house-heating practice, 35M cu.ft. of 400 B.t.u. gas are the equivalent of 1 ton of anthracite or of high-grade bituminous coal.

Assuming that the costs per ton delivered on cars to a retail yard are \$10 for anthracite and \$5 for high-grade bituminous coal, and that yard expense, overhead charges and net profit combined, average 25 per cent of these costs, purchasers would pay, *at the dealer's yard*, \$6.25 per ton for bituminous coal and \$12.50 per ton for anthracite.

With the above prices at the seller's premises, the householder requiring 12 tons of anthracite or bituminous coal, or its gas equivalent, to heat his home satisfactorily through the heating season, would pay each year for fuel at the seller's premises as in Table I.

TABLE I—Cost of Fuel at Gas- or Coal-Yard

Anthracite.....	\$150
Bituminous.....	75
Gas.....	147

This we will term Item I. The expenses on the consumer's premises, other than for fuel, vary greatly with the kind of fuel used, and many of these expenses with coal are often overlooked. When solid fuel is burned, storage room for coal, ashes, and kindling must be provided; the additional cost of this space in a house where 12 tons of coal are stored and burned each year will be not any less than \$400, assuming a concrete floor and concrete or brick walls and may be much more. The yearly charges in such an investment—not required where gas is used—are as in Table II.

In the cost of delivery of fuel to his residence from the seller's premises, the gas consumer fails to get the same square deal from the public that the coal consumer enjoys. For the delivery of solid fuels, the public provides a free highway, generally paved, paid for and maintained by taxes, a share of which are

paid by the gas merchant and collected from the gas consumer in every gas bill.

The coal consumer is required to pay the coal merchant only the actual costs involved in such delivery.

TABLE II—Interest on Cost of Cellar Space and Other Costs Accompanying Use of Fuel

	Anthracite	Bituminous	Gas
Interest on cost of cellar space at 6 per cent.....	\$24.00	\$24.00	0.00
Depreciation at 3 per cent.....	12.00	12.00	0.00
Taxes at 2½ per cent.....	10.00	10.00	0.00
Interest on cost of delivered coal at 3 per cent (6 months).....	5.13	2.88	0.00
Total capital charges per year on investment not needed with gas.....	\$51.13	\$48.88	0.00
Removal of ashes not needed with gas.....	4.00	4.00	0.00
Damage to property caused by smoke and soot....	0.00	40.00	0.00
Item II, total of above items.....	\$55.13	\$92.88	0.00

As these costs seldom exceed \$1.75 per ton from yard to consumer's cellar, this sum will be assumed as the delivery cost per ton for anthracite or bituminous coal. The corresponding average cost of the actual delivery of gas from seller's to consumer's premises may be safely estimated about as in Table III.

These delivery costs of each kind of fuel for the season are set forth in Table IV.

This we will term Item III. Tabulating the foregoing items we obtain the comparative costs of heating the home for the year contained in Table V.

Obviously, under such cost conditions, householders, whether they employed a janitor or not, would quickly turn from both anthracite and bituminous coal to the

cheaper, safer, cleaner and vastly more convenient gas. But, unfortunately for the gas consumer, these conditions do not exist. Instead of providing for the gas consumer a free highway for the delivery of his fuel, as we do for the coal consumer, a highway for gas is provided by private investors and this highway is heavily taxed by city, county and state.

In consequence the gas consumer is required to pay

TABLE III—Cost of Delivering Gas to Consumer

	Per M Cu.Ft.	Per ton of Coal Equivalent
Power for pumping gas.....	0.01	0.35
Unaccounted for (leakage, etc.).....	0.03	1.05
Meter expense.....	0.01	0.35
Totals.....	0.05	1.75

tolls for the passage of his fuel through the gas turnpike. These tolls, of necessity with such a system, must pay all charges for interest, depreciation, taxes and maintenance. As the actual investment in a city gas distribution system may be safely estimated at \$1.50 per thousand cubic feet of gas delivered and sold per year, the gas highway tolls will be as in Table VI.

Adding this expense for gas to the comparative costs previously stated, we obtain the comparative total costs given in Table VII.

From this analysis of the various items making up the total comparative costs of house heating with anthracite, bituminous coal and gas, it is quite obvious that unless the handicap of highway tolls borne by the

TABLE IV—Delivery Costs of Twelve Tons of Fuel

Anthracite.....	\$21
Bituminous.....	21
Gas equivalent.....	21

gas consumer is eliminated or greatly reduced, house heating with manufactured gas will continue as at present, a convenience for those only who can and will pay for such a luxury.

This gas highway toll charge which is the greatest economic barrier against the general substitute of gas for coal in house heating, is unfair in the competition between gas and coal; it is unjust as between land owners and gas consumers; it is unnecessary and its elimination would tend to the rapid abatement of the smoke nuisance, which in many cities causes damages totalling from ten to twenty dollars per capita each year.

For the public to provide a free highway for the delivery of coal, coke and oil from the merchant's to

TABLE V—Actual Fuel Costs as Heretofore Considered

	With Anthracite	With Bituminous	With Gas
Item 1, cost of fuel at seller's premises.....	\$150.00	\$75.00	\$147.00
Item 2, comparative costs on consumer's premises.....	55.13	92.88	0.00
Item 3, Actual delivery cost—12 tons coal or gas equivalent.....	21.00	21.00	21.00
Item 4, total of above items.....	226.13	188.88	168.00
Item 5, labor, if janitor is employed.....	60.00	60.00	0.00
Item 6, total.....	\$286.13	\$248.88	\$168.00

the consumer's premises while compelling the gas consumer to pay highway tolls for the delivery of his gas, is clearly to maintain an unfair competitive condition.

Equity requires that the land owner should pay for the financial benefit which he can, or does, receive from

the presence of a gas distribution system through which gas may be delivered to the occupant or purchaser of his land; if he rents his property he collects higher rent where gas service is available than where such service is lacking; if he sells a lot where gas service is available, he gets a price higher than the sum of the price of a similar lot where gas service could not be obtained, and that part of the entire cost of the gas distribution system of the city which could equitably be charged against the lot in question.

As the gas company and not the land owner has paid for the gas highway, the gas consumer pays gas highway tolls twice; he pays them in higher rent to his landlord, or their capitalized value in a higher price if he buys the lot; then as the gas company has not received the money, he pays again in tolls on the gas he consumes. That the land owner should get something

TABLE VI—Highway Toll Gas Must Meet

	Per M. Cu.Ft.	Per Ton Of Coal Equivalent
Interest on \$1.50 at 7 per cent.....	\$0.1050	\$3.675
Depreciation on \$1.50 at 3 per cent.....	0.0450	1.575
Taxes on \$1.50 at 2½ per cent.....	0.0375	1.3125
Maintenance at 2½ per cent.....	0.0375	1.3125
Total highway tolls.....	0.2250	7.8750
Item 5, Gas highway tolls on gas equivalent of 12 tons of coal.....		\$94.50

for nothing while the land occupier and gas consumer has to pay twice for the use of the gas highway is an injustice which becomes obvious upon consideration of the facts. If and when this injustice and its effects are clearly understood by gas consumers, gas distribution systems generally will be purchased from their present owners and the cost assessed against the land values benefited by their presence. Thus the tolls on the gas highways may be abolished, and manufactured gas will be enabled to assume its rightful place as the cheapest, cleanest, safest and most convenient fuel for house heating.

TABLE VII—Complete Costs When Using Any One of Three Fuels

	Anthracite	Bituminous	Gas
Item 4, Previous total—no labor charge.....	\$226.13	\$188.88	\$168.00
Item 5, Highway tolls for gas.....			94.50
Item 6, total comparative costs without labor charge.....	\$226.13	\$188.88	\$262.50
Item 3, labor firing.....	60.00	60.00	
Item 7, total comparative costs including labor.....	\$286.13	\$248.88	\$262.50

Incidentally also the elimination of the monopolistic feature of ownership and control of the gas highway, from the business of gas companies, would make unnecessary much of the political interference with the service functions of manufacturing and selling gas, and probably the danger of municipal ownership and consequent political mismanagement of the gas industry would disappear.

COALDEX is a pamphlet published by H. E. Friend, of 177 Church Street, New Haven, Conn. The subtitle of this little book is "A practical method for determining the value of bituminous steam coal." It gives charts for determining the relative value of competing coals from their specifications. It endeavors to answer the question: Which coal shall I buy? Paper cover, 20 pp., 9½x12½ in., \$3.

# Fitting Latest Switchboard Appliances to Mine Generators and Converters

Only Such Equipment as Gives Protection Against the Most Frequent Delays Is Needed — Simple Apparatus Requiring Few Adjustments Preferable — Thermal Relay Permits More Efficient Use of Generating Machinery

By W. L. NEWMAYER\*  
East Pittsburgh, Pa.

**C**HIEF AMONG the requisites of automatic switching equipment for mine service are reliability and simplicity. Reliability of operation, particularly in the mining field, can be obtained only by the use of rugged and substantial apparatus which will function properly under mine conditions which unfortunately are always adverse to satisfactory service. The equipment must be positive in operation, as nearly trouble proof as possible, and should not be affected by external conditions such as heat and cold. Finally, the apparatus must be adequately protected against abnormal conditions by suitable protective devices. It is fairly simple to supply equipment which will automatically start a motor-generator set or synchronous converter under normal conditions, but it is not so simple to provide such equipment, with the addition of protective features, which will protect positively against any trouble which may occur.

However, continuity of service can be obtained without highly complicated or intricate apparatus. Once reliable operation and adequate protection are assured it is a mistake to add special features, particularly to mine equipment where simplicity is desirable. Additional protective apparatus means more possible places of failure, more expert maintenance supervision and

complications not warranted in most mine operations.

As a rule, the single-unit substation, which has only one motor-generator set or converter, is the most desirable. By placing single units at various points inside or outside of the mine the voltage at all points can be kept well up to normal without investing heavily in copper for feeders. The equipment is also simpler than that of a two-unit station, as special apparatus for paralleling two machines in the same station need not be provided.

The service requirements of an automatic substation are not always the same. One operator may want a highly flexible and complicated control, requiring perhaps one machine to operate all the time and a second to start up, on load demand, with provision for interchanging machines, etc.; while another may go to the other extreme and require the elimination of protective features which never should be omitted in an unattended station. Undoubtedly there are applications where double-unit stations with low-voltage and load-demand starting, etc., should be supplied. However, it will be found that in the majority of cases the single-unit stations with the following features of control and protection will be the most satisfactory:

(1) Remote control by means of a push-button station which may be located as far as several miles away from the substation and connected to it by two control

\*Switchboard Engineer, Westinghouse Electric & Manufacturing Co.

FIG. 1

## Automatic Panels

This outfit controls a 150-kw., 2,200-volt, three-phase, 60-cycle, 275-volt direct-current motor-generator set. The alternating-current oil circuit breakers are mounted directly behind the left-hand and center panels. All that can be seen of these breakers are the clapper control mechanisms for starting and running them. The direct-current circuit breaker automatically opens and recloses. The thermal relays are in the upper part of the middle panel.

FIG. 2

**Underground Station**

Automatic equipment for use at mines must be reliable and simple. Power delays are always of serious consequence to the mine operator, therefore he must be well equipped with apparatus which will rarely fail. Mine conditions are such that complicated devices cannot always be given necessary care and supervision, hence, protection against troubles which rarely occur should not be indiscriminately provided.

wires of sufficient capacity to carry only the small current required to actuate the starting relay.

(2) Full automatic control by means of a time switch which will start the station at a predetermined time each day and will shut it down at another predetermined time. The time switch may be equipped with the Sunday cutout attachment which will prevent operation of the substation one day a week. Such a clock need be wound only once a week. The station runs continuously, regardless of load during the period the control circuit is energized.

The source of control for operating the various relays is obtained from a small operating transformer energized from the incoming alternating-current line. The direct-current circuit breaker is of the service-restoring or automatic reclosing type which opens on overload and recloses when the circuit resistance to the load rises to a limiting value.

A station is "locked out" when its equipment is not only shut down but prevented from restarting until an inspection is made and the trouble cleared. Motor-generator sets are usually provided with the following protective features which "lockout" the station in case of trouble: (1) Heavy alternating-current overload not quickly relieved by the opening of the direct-current circuit breaker, (2) failure of the set to start properly or continued operation of the starting auto-transformer or compensator, (3) overheating of machine bearings and (4) reversed polarity of the generator especially if it is feeding into a system also fed from some other source.

The motor-generator set is only temporarily disconnected in case of the following: (1) Alternating-current supply failure or low voltage, (2) phase failure or phase reversal, (3) overheating of windings due to long continued moderate overload, (4) loss of generator or motor field and (5) reverse current. When any abnormal condition causing the disconnection of the set is removed, the equipment is automatically made ready for service or restarted.

Fig. 1 shows a typical mine substation equipped with an automatic switchboard for controlling a motor-generator set. The apparatus is mounted on a switchboard 76 in. high with a total width of 80 in. On the left-hand and center panels are mounted the clapper

control mechanisms for the starting and running alternating-current oil circuit breakers, the breakers being mounted directly behind the panels. At the top of the first panel are the two alternating-current, induction-type overload relays. At the extreme top of the panels is the control relay for the breaker mechanism.

On the upper part of the second panel are the two

**Fig. 3—Mine-Service Type Automatic Panel**

Compact types which can be set up in small rooms are popular in some regions. This panel shows the complete alternating-current and direct-current switchboard equipment. The oil circuit breakers are isolated on a separate pipe-frame structure.

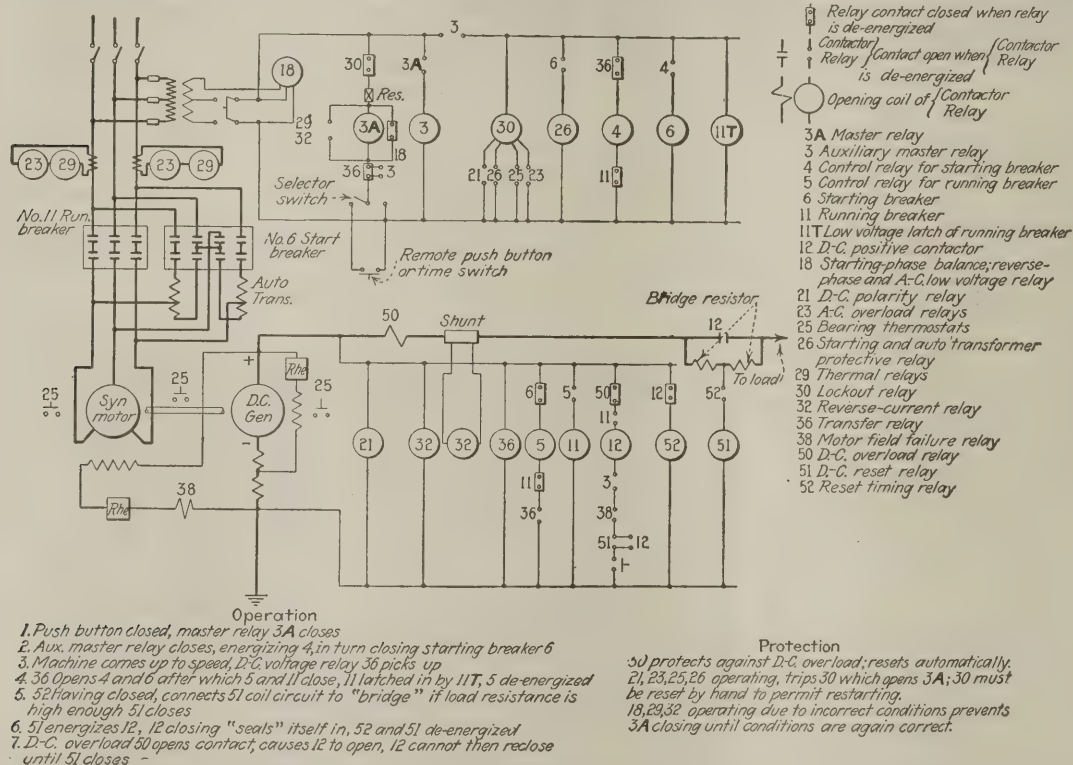

thermal relays, the starting-phase-balance-reverse-phase relay and alternating-current induction-type low-voltage relay. Near the larger control clapper is a control relay for the running breaker mechanism.

The panel on the right is the direct-current and sequence relay board. At the top can be seen the main direct-current contactor with overload and time delay relays on either side. The time-delay relay prevents the direct-current contactor from reclosing until a definite period has elapsed after it has opened. The direct-current voltmeter and ammeter are the round instruments. Below the meters, on the left, are the direct-current reset relay for measuring the feeder-load resistance, the master-control relay which is actuated by the distant-control push-button switch, the starting timing relay for protecting against excessive running on the auto transformer or failure to start properly, the field failure relay which prevents operation in case of field failure, and, on the right, the lockout relay which is actuated by the protective devices to lockout

Also a push-button station is supplied for the control of the substation from a distant point.

A still more compact design is shown in Fig. 3. The oil circuit breakers are mounted on a separate switchboard on a simple pipe structure. Thus all the high-tension equipment easily may be isolated. This switchboard consists of only a single panel with all the necessary relays, etc. The apparatus is substantially the same except that the auxiliary transfer relay has been eliminated. This arrangement greatly simplifies the switchboard and wiring. The lockout relay, shown on the left of the panel, has annunciator dials which indicate which device has shut down the station when a lockout occurs. The reverse-current and polarity relays, not shown, when required, are added on the sub-base panel.

The sequence of operation is quite simple and may be understood by referring to the schematic diagram, Fig. 4. Ordinarily the selector switch is thrown to the left, so that the station is controlled by the push-button

the station. The push-button switch on the left may be used to open the direct-current contactor without shutting down the set, while the voltmeter switch permits reading either the generator or feeder voltage. The single-pole double-throw selector switch in one position controls the set directly from the switchboard; in the other position it permits its control from the distant push-button switch.

The three relays at the bottom of the panel are respectively, the auxiliary master relay, the transfer relay and the auxiliary transfer relay which causes the transfer from the starting to the running breaker when the motor has reached synchronous speed.

When the generator is to feed into a system which also receives power from another source the sub-base section is added to the right-hand panel on which is mounted a direct-current polarity relay and reverse-current relay.

Apart from these panels is a small control transformer for supplying power for the control circuits.

switch. The closing of this switch energizes the master relay 3A which in turn closes auxiliary master relay 3. When 3 closes, the starting breaker 6 is closed by its control relay 4. The motor now being connected through the auto transformers to the line, starts on reduced voltage and comes up to speed. The motor field is connected directly across the armature of the generator, and the induced current in the field tends to prevent the generator voltage from building up. As the motor comes up to speed this effect is lessened, and the generator voltage slowly increases. The generator voltage does not increase proportionately with the speed, therefore it may be used as a safe indication for transfer of the motor to the full alternating-current pressure. The direct-current voltage relay 36, connected across the generator, is set to operate at approximately 80 per cent normal voltage and causes the starting breaker relay 4, and the starting breaker 6, to open, also the running breaker relay 5, and the running breaker 11 to close. The running breaker 11 is

Fig. 5—Thermal Overload Relay

This device is one of the most important protective instruments used on automatic panels. The ordinary overload relay often shuts down a mine substation too frequently. Rarely is the all-day load near the full heating capacity of the generator.

held closed by the low-voltage release 11T; relay 5 and closing coil 11 being de-energized.

When the running breaker is closed and the motor field current is normal the direct-current contactor 12 will close if the feeder resistance is high enough to limit the load to a safe value. This is indicated by the closing of the reset relay 51. If, however, the load resistance is too low this relay prevents the closing of the direct-current contactor.

Should a direct-current overload occur contactor 12 opens by the operation of overload relay 50. A timing relay 52, then closes its contacts after a definite time, bringing into action the reset relay 51 which, in turn, closes or holds open contactor 12 as already explained.

As stated, an automatic switchboard and its accessories not only has the ordinary alternating- and direct-current overload protective relays but also low-voltage and reverse-current protection and other special protective features, which give to the automatically operated station better protection than those which are manually operated. Many of these relays anticipate trouble, they shut down the equipment before serious damage occurs. A short description of the design and operation of the more special relays will be of interest.

The starting-phase-balance-reverse-phase and low-voltage relay is a polyphase induction-type instrument with the windings so designed that (1) the voltage

on the three phases must be approximately balanced, (2) the phases must be of the correct rotation and (3) the voltage on the three phases must be at least 80 per cent of normal to cause the relay to function. It is so connected with the automatic control wiring that the motor-generator set cannot start unless these conditions are correct.

One quite common misapplication of this type of relay has been made in the past. An attempt has been made to use it to protect a polyphase motor from single-phase operation when the motor is running. It ordinarily will not give this protection for the reason that a phase failure on an incoming line will not unbalance the voltages of the three phases of the motor winding appreciably. The motor will operate from a single phase and act as a generator on the other two phases, thus holding up the voltage to nearly normal on the open phases. The relay, naturally, under these conditions cannot detect the phase failure. Its function is to prevent starting or attempting to start under improper conditions. Positive protection against single-phase operation is provided by the use of two thermal relays as explained below.

The thermal overload relay, shown in Fig. 5, is connected in the secondary circuit of the incoming line current transformers. It consists of several spiral bimetallic springs attached to a shaft so that, as they heat and twist, due to unequal expansion, they turn the shaft and close the contacts. The heating is proportional to the current in the line wires and therefore proportional to the load on the motor-generator set. The whole element is immersed in oil and sealed in a brass case, which is surrounded by a heat-insulating sleeve. The design is such that a certain amount of current flowing for a given length of time causes the contacts to close.

If a motor is operating on a single phase, and the loaded phase is beyond the capacity of the winding, the relay in this phase quickly shuts down the machine and saves the winding. The thermal relay also has an advantage over an instantaneous acting phase-failure relay in that a momentary phase failure, which will not harm the machine, will not cause the motor-generator set to shut down. After the relay and motor windings cool the set will restart automatically if the three phases are again balanced.

Just below the babbitt at the bottom of each bearing is located a bearing-thermostat bulb. In this bulb is a liquid which vaporizes and exerts pressure at a fairly low temperature. This pressure is transmitted through a copper tube to a copper bellows which is expanded by the increasing pressure. The elongation of the bellows operates the contacts of the relay which in turn causes the station to shut down. The thermostat, once operated, must be reset by hand so that the maintenance man can see at once which bearing has overheated. The thermostat is designed to operate at about 100 deg. C. which is high enough to prevent it from shutting down the equipment in normal service but low enough to insure operation before there is danger of the bearing being destroyed.

Fig. 7—Thermostat Switch and Bellows

The heat generated in a bearing is transmitted to a bellows which expands and causes a small switch to open the control circuit.

Fig. 6—Bearing Thermostats Check the Oiler

Protection must also be provided against mechanical failures. A damaged bearing is usually as serious as an electrical breakdown.

of water used is comparatively large the head is small. Fig. 2 shows an actual installation of three of these machines in the No. 1 breaker of the Pennsylvania Coal Co. at Dunmore, Pa. In this installation each pump is driven by a 3-hp. motor and handles about 320 gallons of water per minute against a head of approximately 4½ ft., or a pressure of about 2 lb.

The screens in these machines measure about 18½x24 in. and about 15 tons of buckwheat No. 1 are fed to them per hour. This gives, on the average, about 12½ tons of clean coal and 2½ tons of slate and rock. A long series of tests gave the following results on the separation performed:

Average coal in slate.....	6.7 per cent
Average slate in coal.....	7.4 per cent

The coal carried over with the slate and comprising the percentage given above consists of two products, namely, pure coal and heavy but burnable bone. Separating the combustible material in the slate into these two constituents gives the following results:

Average pure coal in slate.....	3.7 per cent
Average heavy bone in slate.....	3.0 per cent

The results given represent average practice with these machines. By changing the adjustments and making them such that a slightly larger percentage of combustible material would be carried into the refuse it would be entirely possible to secure a cleaner coal product. Conversely, adjusting the machines to give a

cleaner rock product would put more slate in the coal. In this connection, however, it should be remembered that any small coal containing less than 5 per cent of refuse is today called a "special" product and commands a premium over the regular market price.

#### SIMPLICITY, LOW COST AND SPACE ECONOMY

The chief advantages of this machine, aside from the excellent work done as has already been enumerated, are its small size, large capacity, great simplicity, and low first cost. From Fig. 2 it will be noted that a battery of three of these machines occupies a floor space of only 12 ft. 1½ in. x 14 ft. When it is considered that each of these machines handles approximately 15 tons of coal per hour the significance of these figures becomes apparent. The simplicity of the device needs no comment, as this is self-evident from the drawings. And naturally, small size and simplicity mean low first cost.

The chief disadvantage of the machine is the large quantity of water that it uses. This is, however, more apparent than real. As previously stated this machine uses approximately 320 gallons of water per minute. This quantity of water is circulated rather than consumed as it is used over and over again, only the makeup water necessary being added. Actual consumption is thus small, as are also the power requirements, each pump being supplied with only a 3-hp. motor as previously stated.

## Gasoline-Driven Generator Runs Hoist And Fan in Emergency

BY ED GUNIA

Master Mechanic, Monarch Fuel Co.,  
Rural Ridge, Pa.

THE present-day reliability of self-starting and ignition equipment on gasoline engines recommends them for emergency use when there is a protracted interruption in the flow of current from central power stations. For that matter a steam-driven standby unit also might be kept available for immediate use, but it has the distinct disadvantage of being expensive to maintain, especially where there is no bathhouse or central heating system to utilize the steam pressure that must be maintained continuously.

Having in mind a twofold purpose, first to get its men out of the mine and secondly to keep the fan going when the purchased power is interrupted for any great length of time, the Monarch Fuel Co., at Rural Ridge, Pa., recently installed a 100-kva., 2,400-volt generator driven by a 225-hp. gasoline engine. The power generated by this unit can be used to operate the cage in the supply shaft until all the men are out of the mine, and then it can be switched to run the fan. The change in power is readily effected after the emergency generator is in motion, merely by throwing out the main switch and throwing in an auxiliary switch on the plant end of the bus-bar.

Only one motor is required to drive the fan, whether the latter be operated by purchased power or that coming from the gasoline-driven generator. The 5x11-ft. fan is driven by a two-speed motor, which has a capacity of 37.5 hp. at 430 r.p.m. and 100 hp. at 870 r.p.m., usually developing 110,000 cu.ft. of air.

Normally the hoist is driven by a 150-hp. induction

Gasoline Engine Replaces Purchased Power When Current Fails

Hoist, normally driven by 150-hp. induction motor, is operated by 50-hp. motor when purchased power is not available. Fan cannot be driven till men are all hoisted. Then fan is operated by gasoline engine using same motor as is in use when purchased power is being used.

motor with a speed of 440 r.p.m. As the capacity of the standby generator is not sufficient to drive the main motor of the hoist, a 50-hp. auxiliary induction motor with a speed of 870 r.p.m. is provided. The latter drives the hoist by a chain and a sprocket on the shaft-coupling between the hoist and the main motor. This sprocket is idle when the main motor is in operation and can be bolted in a few minutes to one flange of the shaft-coupling when purchased power for any reason is interrupted.

## News Of the Industry

### Need of Fundamental Coal Information Emphasized During Present Depression

Lack of Government and Association Data Responsible for Guesswork  
Statistics—Benefit Expected from Elimination of Uneconomical  
Mines—Export Trade Offers Big Opportunity

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Economists, public and private, are giving an unusual amount of study to the problems of coal. The industry is passing through its worst depression. Foundations are being laid for fundamental changes. It is recognized that tests by fire are productive of some good. The hope is that the destructive forces of the present situation can be meliorated to the greatest extent possible.

An example of the benefits to the industry which are resulting from the depression is the elimination of uneconomical mines. They are being eliminated with all the ruthlessness that characterizes the direct application of the irresistible force of economic law. These mines are going on the bargain counter in increasing numbers at prices which thoroughly justify the statement that they are being sold for a song. In that connection, however, it is pointed out that there is nothing strange in the sale of coal mines at such sacrifices when the spot price is lower than at any time since 1916.

When account is taken of the various wage advances which have taken place since 1916, the unremunerative character of the present coal price is accentuated. Crushing as are the losses which individuals in the industry are suffering, the coal industry is not unfamiliar with these periods when only the fittest survive. The spirit of the industry is strengthened by the necessity of surmounting new obstacles.

#### Statistical Guidance Much Needed

One of the great difficulties in meeting these obstacles is the lack of fundamental information. A large amount of the data which have been gathered by the local associations and on a national scale are not now available. The situation is serious because there never was a time that the coal industry had the statistical guidance essential to its thoroughly intelligent conduct, but the volume of statistics formerly available constituted a veritable plethora of essential data as compared with that obtainable now.

The outstanding, crying need of the industry, however, is for a stock report. Among the operators the feeling is that

stocks are very much lower than is indicated by the various guesses being made. When the fundamental importance of coal is considered it would seem, many point out, that the greatest industrial nation in the world would have available information of this importance. Statistics are most needed in troublesome times. In actual practice, however, the coal industry produces its greatest amount of statistics when they are least needed, and when they are greatly needed the available figures are almost negligible.

#### Better Utilization Is Important

Enough data are available, however, to determine the fact that the state of industry is not alone responsible for the decrease in the volume of consumption. Better utilization of coal is a more important factor than is generally realized. No small amount of coal has been displaced by fuel oil and some reduction in the amount of coal required has resulted from the elimination of small isolated power plants with the growing availability of electricity. Some further losses of coal market are attributable to the development of hydropower.

There are many who think that a portion of our surplus capacity could be occupied were determined efforts made to expand our foreign trade in coal. Much more American coal could be exported were the exporter to expand his business beyond trade in coal alone. It is pointed out that the companies that are making the greatest success of foreign trade are importers as well as exporters. To be assured of return cargoes they invest in foreign tonnage-producing enterprises. In this way and by becoming general traders they are in the position to insure a steady and dependable market for the exported commodity, which constitutes the concern's major interest. It will be recalled that F. R. Wadleigh, formerly Federal Fuel Distributor, for years has been urging return cargoes for ships taking American coal to foreign ports. In his opinion our failure to export more coal has been due to failure to give proper attention to obtaining return cargo.

### Ford's Road Pays 12 per Cent To Employee Investors

The Detroit, Toledo & Ironton R.R., Henry Ford's road, earned 6 per cent on the investment during the first half of 1924, or at the rate of 12 per cent annually, according to an announcement on July 29 to employee stockholders.

Since Nov. 1, 1923, when the railroad launched the plan, the employees have purchased \$162,994 of investment certificates of the road from their earnings.

### Federal Suit for Demurrage At Hampton Roads Piers A Surprise to Operators

The action of the Railroad Administration in making a new attempt to collect bills for demurrage at Hampton Roads during the period of the Fuel Administration comes as a complete surprise to the coal operators who participated in those pools. The matter was gone into thoroughly during the administration of Director General Hines and the bills against the individual operators were withdrawn definitely. Now, after three years, counsel for the Norfolk & Western, the Chesapeake & Ohio and the Virginian Ry., on behalf of the Railroad Administration, are beginning suits to recover some \$500,000 of war-time demurrage charges.

At the time the demurrage was assessed, control of the movement of the coal was in the hands of the Fuel Administration. Car movements were in the hands of the Railroad Administration. The movement of boats was in the hands of the Shipping Board. While the operators were compelled to put their coal in the pools, they had no control over the situation which resulted in the assessment of the demurrage.

It happens that the last thing E. J. McVann did before resigning as secretary of the Smokeless Operators' Association was to convince Director General Hines that the operators were not responsible for this demurrage. Now that he has resumed the office of secretary, his first duty is to go over the whole ground again with James C. Davis, the present Director General. The whole question involved is whether or not one government agency can compel the payment of penalties incurred under compulsion of other government agencies.

## Anthracite Operators to Teach Public How to Heat Homes with Small Sizes

A program of public education on the economy and usefulness of anthracite is to be set in motion by anthracite operators. It will consist of four permanent service stations, one each in New York, Philadelphia, Boston and Washington, where coal consumers may go for definite information on the proper methods of heating a home. These permanent clearing houses of information will be known as Anthracite Economy Service, with every indication that "service" will be rendered with unusual completeness.

A further step in the campaign of public enlightenment will be a traveling exhibit, known as the Anthracite Economy Service Exhibit, with the same broad purpose as its keynote. It will be shown in twenty different cities, a week in each, starting at Portland, Me., the first week in September.

The Anthracite Economy Service will build upon and extend the scope of past efforts to educate the public also in the wider use of smaller sizes, particularly buckwheat. A convincing into-the-home message will be carried to every part of the anthracite-consuming territory special attention being given to encourage the housewife to visit the Service and Service Exhibits. Both dealers and appliance manufacturers have agreed to co-operate.

The first step will be the opening of the four permanent information bureaus, each one showing complete installations of standard devices for the use of buckwheat coal. The personnel of the demonstrating force retained by the operators is the highest; men equipped by experience and training to prove the economy and efficiency of both the coal and the appliances, will be in constant attendance.

The unique traveling exhibit, like the permanent service stations, will be given plenty of publicity and with the dealers co-ordinating it should make a direct appeal to the great body of consumers. As in the case of the permanent service, considerable effort will be spent in showing the home owner and the housewife how to get a maximum of heat in the furnace or the boiler. This will apply particularly to buckwheat, although the broad idea is to show the public how to use anthracite to the best advantage. The extension of the use of buckwheat coal in the small home, however, is the objective directly aimed at.

All of the approved equipment designed for the average dwelling will be shown at all the exhibits. It will include the very newest device, a moderately priced, compact and most efficient unit, including a special grate, blower and automatic control, for burning buckwheat in the smaller size home. Friends of this new device for attaching to the average heater believe that it will play a large part in promoting the sales of small-size anthracite.

Nothing will be sold at either the permanent Anthracite Economy Service Exhibits, their purpose being purely educational. The service will be free to the public.

## Who Dirtied Up This Coal?

Mine 18 of the Western Coal & Mining Co., in Southeastern Kansas, is shut down after a set of rather interesting events. The mine has been delivering coal to the Missouri R.R. on contract. The railroad refused coal because it was too dirty. The mining company could not remedy the situation by placards and requests, so it shut down the mine. This brought some thoughtful miners to their feet, so to speak. They offered to discipline those of their number who were considered responsible for the dirt. But the district union officials wouldn't hear of this. They demanded that Commissioner W. L. A. Johnson, of the Southwest Interstate Coal Operators Association, compel the company to pay each miner \$1 a day for the shutdown. Mr. Johnson refused. So the mine is still down and the argument goes merrily on, while the miners go hungry and the railroad gets coal elsewhere. It is merely one of these occurrences the union mine operator faces every now and then.

## British Miner Worse Off Than American, Kennedy Finds

Writing from Dublin, Ireland, Thomas Kennedy, of Hazleton, Pa., president of District 7, United Mine Workers, describes the results of his investigation of conditions, wages, etc., in England, Scotland and Wales.

"The Miners' Federation of Great Britain, which includes Wales and Scotland," he writes, "has about one-third less members at this writing than it had immediately following the war and up to the strike of 1921. The disastrous ending of the 1921 strike is given by miners' officials as the cause of the decline in membership. The wages of the miners today are about 10s. less than the wages received during the war, or about \$2.50 per day in American money. The wages now being received in Scotland and Wales and generally in England by the mine workers are as follows: Outside top laborers, \$9 per week; inside day laborers, \$2 per day; tonnage miners, which corresponds to our contract miners, are earning on the average of \$3.50 per day. And all time is not being worked by any means. . . .

"We met Hugh Crankshaw, formerly general manager of the Lehigh Coal & Navigation Co., who also was at Cranberry and Harwood. Crankshaw designed and constructed the coal mine at the British Empire Exposition at Wembley, which is a marvelous piece of work and which attracts more attention than any other exhibit. He is located at South Wales, but not now in the operating business, although he is soon to take charge of the largest coal-mining property in Great Britain which will be known as the Anthracite Consolidated Collieries, all situated in South Wales."

## Davis Denies Owning Stock In Any Coal Mine

John W. Davis, Democratic candidate for President, denies that he is interested in non-union coal mines in West Virginia, or that he was one of Charles G. Dawes' "minute men," in a letter printed by a Sullivan (Ind.) newspaper July 29. The letter was sent in reply to a communication from the newspaper made at the request of union coal miners in Indiana. The letter, in part, is as follows:

"I own no stock whatever in any coal mine, union or non-union, or, for that matter, any coal or coal lands. I was never one of Charles G. Dawes' 'minute men.' I have never been opposed to labor unions, and thoroughly believe that they are necessary to the welfare not only of the laboring man but the community as well."

The Rev. Norman Thomas, the Socialist candidate for Governor of New York, launched an attack on Mr. Davis July 30 for his alleged silence on "the continued denials of civil liberty and the right to organize" in West Virginia.

"It seems to me to be an extraordinary state of affairs," said Mr. Thomas, "when it is recommended to labor organizations that a Presidential candidate should not be opposed because he favors the existence of labor unions and does not happen to own stock in a non-union coal mine. Coal stock in bituminous mines is very unprofitable anyway, and Mr. Morgan's attorney probably has better investments."

"The labor complaint against Mr. Davis is that he has never used his great ability constructively for the interests of the people. He accepted without a word of protest the support of the West Virginia delegation, which contained Sheriff Don Chafin, of Logan County, the most autocratic tool of absentee ownership in America."

"As a nominal West Virginian Mr. Davis never protested against the continued denials of civil liberty and the right to organize which has made West Virginia's record a blot on the American escutcheon. In the face of these facts Mr. Davis' letter is ridiculously inadequate."

## New Kentucky-Indiana Railroad May Be Built

The newest railroad project in the Midwest is the proposed Owensboro, Rockport & Chicago Ry., to run 84 miles from Owensboro, Ky., across the Ohio River and north to Elnora, Ind., making a connection with the Chicago, Terre Haute & Southeastern, which is a part of the Chicago, Milwaukee & St. Paul Ry. If this line is built it may offer a new outlet northward for Kentucky coal, especially from the western Kentucky field. The company is now capitalized at \$20,000 with expectations of increasing this to \$2,500,000 if the Interstate Commerce Commission grants the petition filed this summer for the right to build. The officers of the company are: President, E. T. Franks; Vice-President, D. C. Stimson; Secretary, E. W. Smith, all of Owensboro.

## Coal-Mine Accidents in June Kill 161 Miners; Six Months Toll Is 1,302

Accidents at coal mines in the United States during June, 1924, resulted in the death of 161 men, according to information received from State mine officials by the U. S. Bureau of Mines. The output of coal during the month was 38,151,000 tons; hence the fatality rate was 4.22 deaths per million tons of coal mined, as compared with 3.36 for the previous month, 3.73 for June last year and an average fatality rate of 4.22 for the month of June during the 10-year period 1914-1923. For anthracite mines alone the number of fatalities in June was 53 and the fatality rate was 6.88 per million tons, as compared with 6 for the same month last year and 7.06 for June during the 10-year period. For bituminous mines alone the June rate for 1924 was 3.55 per million tons, as against 3.30 for June last year and 3.68 average for June during the 10 years.

Records for 1924 to the end of June show that 1,302 men have lost their lives in accidents at coal mines. Of this number, 1,049 men were killed at bituminous mines and 253 at anthracite mines. The 1,302 fatalities indicate a death rate of 4.76 per million tons, which may be compared with 3.91 for the first six months of 1923. For bituminous mines alone the 1924 rate for six months was 4.61, as compared with 3.59 for the same period of 1923. For anthracite mines alone the rate for the first half of 1924 was 5.51 per million tons, as compared with 5.61 for 1923.

William C. Atwater

President of the New York coal company bearing his name, who was recently elected president of the Pocahontas Operators' Association, succeeding I. T. Mann.

A comparison of the causes of accidents in the first half of 1924 with those for the first half of 1923 shows that explosions of gas or coal dust continue to be the only class of accidents with increased fatality rates. The comparative rates per million tons for the two half-year periods were:

	January to June 1923	1924
Falls of roof and coal....	1.821	1.846
Haulage .....	.644	.607
Gas and coal-dust explosions .....	.601	1.587
Explosives .....	.197	.143
Electricity .....	.117	.120

## Power Show Exhibitors Rush for Space

Over 260 exhibitors have been assigned space at the Third National Exposition of Power & Mechanical Engineering, which will be held in the Grand Central Palace, New York City, Dec. 1-6. As this is more than twice the number that had engaged space on Aug. 1 a year ago, the indications are that this year's show will be of tremendous interest and importance.

As usual, the exposition will parallel the meetings of the American Society of Mechanical Engineers and the American Society of Refrigerating Engineers. The A.S.M.E. meeting will be held in the Engineering Societies Building, 29 West 39th St., New York City, and the A.S.R.E. meeting will be held at the Hotel Astor, New York City. Plans also are under way by the American Society of Heating and Ventilating Engineers to have a gathering of local sections during the time of the exposition. The co-operation of the various engineering societies has been valuable, as it enables members to attend the meetings and at the same time see the interesting exhibits at the power show.

## Chesapeake & Ohio May Acquire Three Small Roads

The Chesapeake & Ohio Ry. on July 25 asked permission from the Interstate Commerce Commission to acquire the properties of the Ashland Coal & Iron Ry., Long Fork Ry. and the Millers Creek R.R., and also authority to assume outstanding obligations of the companies in order to acquire them.

## Coal-Mine Fatalities During June, 1924, by Causes and States

(Compiled by Bureau of Mines and Published by Coal Age)

State	Underground											Shaft				Surface						Total by States						
	Falls of roof (coal, rock, etc.).	Falls of face or pillar coal.	Mine cars and locomotives.	Gas explosions and burning gas.	Coal-dust explosions (including gas and dust combined).	Explosives. ## Lee Says Coal Mines Disrupt Railroad Industry

Interdependence of railroads and mines was emphasized by Elisha Lee, vice-president of the Pennsylvania R.R., at the second annual banquet of the Fayette-Greene Coal Producers' Association, July 31, at the Summit Hotel in the mountains near Uniontown, at which M. D. Cooper, of the Hillman Coal & Coke Co., of Pittsburgh, presided. Mr. Lee said both mines and railroads were subject to wide variations in activity, the carriers even more than the producers of coal. When the coal business is depressed coal operators can close down or stimulate trade by lowering prices. The railroads are so strictly regulated that they cannot do the first at all and the second only when granted permission by the Interstate Commerce Commission.

### Coal Traffic Important Item

The importance of coal traffic to the railroad is immense. That traffic on the Pennsylvania R.R., said Mr. Lee, is three times that of its nearest rival, sand and gravel, and six times that of iron and steel. On the Pennsylvania Railroad, 38 per cent of the traffic is in bituminous coal and 6 per cent anthracite. Of every 10 tons of coal produced 3 tons are consumed by the railroads.

G. W. Galloway, vice-president, Baltimore & Ohio R.R., said that in his forty-one years of railroading he had never seen so friendly a feeling between railroads and the public. Last year the railroads decided to spend 1.4 billions of dollars for better transportation facilities. The program was fairly under way when the volume of business began to decline. At present 300,000 freight cars valued at \$2,500 each and 7,000 locomotives worth fifty to sixty thousand dollars apiece were standing idle, the equipment being worth one and a quarter billion dollars.

### Much Invested in Idle Equipment

Mr. Galloway asserted that the B. & O. R.R. alone has 42 million dollars invested in idle equipment that is in running order and that a non-union territory had shipped 800,000 tons of coal to markets which formerly were supplied by union mines on the B. & O. The average production cost per ton at the open-shop mines is \$1.40 and the freight rate \$1.91, a total of \$3.31. The cost per ton at the union mines is \$2.20 and the freight rate \$1.60, a total of \$3.80, leaving a wide differential on the delivered coal. Coal from this particular field has been shipped all rail to Nebraska. His railroad has a tide-water dock idle in a southern port that cost over \$3,000,000.

Harry L. Gandy, secretary, National Coal Association, said that one-fourth of the revenue of the railroads came from coal traffic and urged that the railroads should not try to "beat down" the price of coal. The gain, said he, from such practices is only temporary and is certain to reflect on the industry by which the railroads largely earn their living.

Fuel, he declared, is no burden on the manufacturer. In 1913 it represented

## No Evidence Anthracite Operators Violate Law

In answer to J. J. Rogers, representative from Massachusetts, Attorney General Stone declares that the Department of Justice has failed in its investigation to find any evidence that anthracite operators are violating the law in the prices they are charging for coal to New England purchasers, and that no immediate action would be taken toward the prosecution of the operators unless damaging evidence is revealed. The Department could find no evidence of a combination or a monopoly to cause a coal shortage or raise the prices of anthracite. The investigation was made at the request of Representative Rogers.

only 2.6 per cent of the total cost of the finished products, and today it should be far less. Overproduction was due to an excessive demand for coal during the war. Walter Barnum, treasurer of the Pacific Coast Co., said the Washington Coal Producers' Association had given careful engineering study to the use of oil and when new buildings and houses were erected the association got in touch, chiefly by letters, with the owners urging the use of coal-burning equipment for heating.

## Utility Coal Consumption and Power Output Drop Again

Electric public-utility plants consumed 2,701,106 net tons of coal during June, according to a report by the Geological Survey. This compares with 2,816,352 tons consumed in May, according to revised figures. Fuel oil consumed by utility plants in June totaled 1,306,140 barrels, compared with 1,207,473 barrels in May.

The average daily production of electricity by public-utility power plants in June was 152,600,000 kw.-hr., or about 1 per cent less than the daily output in May. The seasonal decline during May and June has been greater this year than usual, due to the general industrial depression.

## Erskine Ramsay Donates \$100,000 to Dormitory

To the million-dollar fund being raised for Alabama College at Montevallo, Erskine Ramsay has given \$100,000 to be used toward the construction of a Woman's Dormitory which is to be known as "Janet Ramsay Hall" in memory of his mother. The dormitory will cost about \$220,000. Mr. Ramsay has made his fortune in the operation of mines in the State of Alabama and in the sale of his rights to valuable inventions made by him for the construction of mine machinery. Two years ago he gave an equal sum for the construction of the Erskine Ramsay Engineering Hall.

## Unionization Drive on Again In West Virginia

Another union ultimatum, which may presage disturbances in West Virginia coal mines on a wide scale, has been issued by Van A. Bittner, who was appointed by John L. Lewis, president of the United Mine Workers, to direct union affairs in northern West Virginia. In addressing a crowd of miners at Scotts Run, Bittner stated that West Virginia would be unionized—peacefully if possible, but unionized at any rate.

"We must make union men out of all the scabs on Scotts Run in the regular manner, or by stronger methods if necessary—you know what I mean," he said. Amid the ensuing excitement in the crowd, which numbered close to 6,000, there were loud denunciations of local police officials, coal-mine owners that held out against the union's demands, and even a former Governor of the state.

"We will not stop until Monongalia County—and West Virginia—is 100 per cent union," continued Bittner. "We must preach the gospel of the United Mine Workers. We all know that to spare the rod is to spoil the child. But it is not necessary to try violence. I hope that none of you will attempt violence. We can unionize this field if we will. What group of non-union men is there anywhere that would refuse to join the union if they were pressed to do so by thousands of union members?"

It is reported that similar plans are in the making for the other West Virginia fields lost to the union in the last two years.

Scotts Run has been the center of much violence during the last few weeks. An intensive campaign to unionize the district has been in progress, during which men have been shot down, buildings have been burned and men have been beaten on their way to work. The Scotts Run meeting, however, was not entirely a local affair, for, according to the mine owners, the union officials brought in a large number of union men from Taylor, Harrison and Marion counties, in order to muster a large crowd.

## Export Shipments for Fiscal Year Advance 8 per Cent

Bituminous coal exports during the fiscal year 1924 amounted to 17,203,193 long tons, compared with a total of 15,953,879 tons during the preceding fiscal year, an increase of 7.8 per cent. For the six months, July-December, 1923, bituminous exports were 9,984,305 and for the six months, January-June, 1924, the total was 7,218,888 tons. Exports for the corresponding periods of the fiscal year 1923 were, respectively, 6,783,203 tons and 9,170,676 tons. During the first half of the fiscal year 1924 (July-December, 1923) exports were stimulated by the low production in the Ruhr coal fields, which increased the demand for our coal in Western Europe and South America in particular. This stimulus did not exist during the last half of the fiscal year (January-June, 1924) and exports were 2,765,417 tons or 27.7 per cent less than for the first half of the fiscal year.

## Practical Pointers For Electrical And Mechanical Men

### Simple Tool for Resurfacing Seats of Tube-Hole Covers in Boilers

**Square Piece of Board Is Set on Bit-Brace Shank—  
It Is Covered with Sandpaper or Emery Cloth and  
for Grinding Headers Has a Circular Pilot Block**

Those who have had charge of water-tube boilers at mine power plants well know the difficulty sometimes experienced in grinding in tube-hole caps on the headers. Unless the cap fits the header almost perfectly the joint will leak when pressure comes upon it. Various machines have been devised to perform this work, most of which give excellent results. The mine power plant engineer, however, is often "up against" the proposition of making a tight joint of this kind when no grinding machine is available.

To facilitate performing this operation, the tool shown in the accompanying illustration has been devised. This may be built in any mine shop. It consists of a square piece of  $1\frac{1}{4}$  to  $1\frac{1}{2}$  in. plank *A*, surfaced at least on one side. It should be large enough so that it will a little more than cover a tube-hole opening and the cap seat surrounding it. On one side of this piece is fastened a shank *B* terminating in a square tapered head suitable for holding in a bit brace. On the other side of the block a sheet of sandpaper or preferably emery cloth, *C*, may be attached either by glueing or tacking. For grinding on headers a circular pilot block *D* may be screwed on over the sandpaper or emery cloth.

A convenient way of attaching the emery cloth is shown at *E*. A square piece of cloth is first cut or torn, its length and width being made equal to

that of the block *A* plus twice its thickness. The block is then placed upon this square piece of cloth, approximately centered, and diagonal or miter cuts made from the corner of the block to the corner of the emery cloth. The edges of the cloth are then carefully folded up along the edges of the block and a tack driven in the middle of each side as shown at *F*. The mitered corners may now be folded over and tacked as shown at *G*.

For grinding tube-hole caps the pilot block *D* is left off. In this operation a drill press, a boring machine or any other means of holding and spinning the grinder block may be used with advantage. If covers are held in the hand while being surfaced, however, care should be taken that too much

pressure shall not be exerted between the cover and grinding block, because if much pressure is applied the cover is liable to be jerked out of the hand.

Although grinding the cover seats on headers with a block of this kind revolved in a brace is by no means as rapid as facing them by means of a grinder designed for the purpose, it is much faster than facing with a wooden block and wet sand or with a hand block and sand paper. A variation of the scheme here shown would be to turn and face the block *A* in a lathe, and forge a collar on the shank, against which the back of the grinding block seats. The shank, however, extends through the pilot block as well as a washer and nut, this arrangement being shown at *K*. A sandpaper disk with a hole in its center may then be clamped between the grinding block and the pilot, the paper needing no other fastening. This answers every purpose for surfacing cap seats on headers, but for surfacing the caps a thin washer for holding the sand paper is necessary. Other variations in design will doubtless occur to those operating this tool.

### Box on Casters Facilitates Handling of Armatures

By C. E. REYNOLDS

Superintendent, Allegheny Pittsburgh Coal Co., Logans Ferry, Pa.

The Springdale mine of the Allegheny Pittsburgh Coal Co., Logans Ferry, Pa., has a way to handle heavy armatures, that ought to be adopted by all coal companies having electrical equipment. Spare armatures are kept in wooden boxes on ball-bearing casters, by which means they can be moved by one man from the storeroom to any part of the shop, providing the floor is smooth, as it should be. Faulty armatures are placed in the box from which the spares are removed. It is just as easy, by means of a crane, to lower an armature into the box or to lift it out, as it is to raise it from or lower it to the floor. The scheme eliminates all the labor involved in handling armatures by trucks and also provides a receptacle for storing them.

The bottom of the box is made of  $1\frac{1}{2}$ -in. boards, and the sides, which are nailed to 2-in. inside corner posts, are of 1-in. stuff. Two iron straps are screwed to the sides and the bottom of the box on the outside of the corner posts. The inside of the box may be arranged to allow the armature to rest on its shaft in two end supports or it may be lowered to the bottom.

Castered Box Supports Armatures

#### Emergency Seat Resurfer

This shows the simplicity of construction—a shank to fit a bit brace, a piece of plank, a sheet of sandpaper, a circular block to serve as a pilot and a few tacks and screws are all the materials necessary.

## Anneal Your Boiler Tubes Before You Roll Them

Boiler tubes are fastened in place by being expanded into the header or sheet. The ordinary type of expander consists of three rollers held in a hollow cage through which a tapered mandrel passes. The cage with its rollers is inserted in the tube, the mandrel driven lightly and then revolved by means of levers passing through its upper end or head. This stretches the tube and forces it against its seat in the header or drum sheet.

In order to roll a tube properly and make a tight joint it is necessary to crush the metal of the tube against the metal of the boiler sheet or header. Dirt or grease between the tube and the surface against which it seats is fatal to a good joint. For this reason it is necessary to clean thoroughly both the end of the tube and the inside of the hole into which it is expanded.

Most tube holes in boiler sheets and headers are reamed to size at the factory, and the reamed surface protected from rust, by means of a coating of heavy grease or paint. This must be removed thoroughly before a tube is inserted if a tight joint is desired. The end of the tube, likewise, should be cleaned with a file and all rust and scale scraped or filed off. It is not necessary to polish the end of the tube, but it is essential to secure clean bright metal. In other words, it matters little how rough may be the end of the tube so long as bright metal is exposed.

As sent out from the factory most boiler tubes are merely cut to length and bent to the proper shape if bending is necessary. Particularly if they are to be expanded into a thin sheet—one  $\frac{1}{2}$  in. thick or less—it is advisable to anneal them before expanding. This may be done in an ordinary blacksmith's forge, or if such a forge is not available their ends may be heated in the furnace of another boiler or even in an open fire.

In this annealing process it is necessary to heat only the end of the tube as this is the only portion that is acted upon by the expander. To do this is quite simple. First stuff a piece of waste, a handful of rags or even a wad of old paper into one end of the tube. Build up a good-sized fire or one big enough to thoroughly cover the end of the tube for a distance of about 4 in. Insert the open or unplugged end of the tube and turn it slowly until it shows an even cherry red over its entire circumference. The tube may now be removed from the fire and laid to one side, but so supported that its hot end touches nothing. When cool the other end may be treated in a similar manner.

This simple process is ordinarily all that a boiler tube needs in the way of an anneal. If, however, a particularly soft tough tube is desired, proceed as before but upon removing it from the fire, bury the hot end in air-slaked lime. This will greatly prolong the period of cooling and render the metal soft, tough and ductile.

The object of the plug in the cool end of the tube is to prevent the circulation of air. If it is not used the

entire tube will become too hot to be handled with the bare hand. Again, if the end of the tube is buried in lime the plug should not be removed until the end is cold as otherwise the tube will cool faster than is desirable.

## How and Whys of Processes For Tempering Steel

Every blacksmith knows how to temper ordinary high-carbon or tool steel in the ordinary way, that is, in water. As usually practiced this process consists in heating the tool to be tempered to the required cherry red, plunging it in water, polishing and then "drawing" it to the required color in a muffle or by some other means of heat application. When tempering in oil the process is substantially the same but variations may be introduced.

Certain tools, such as knives and wood-cutters, require what is known as a "spring temper." This corresponds to drawing to a blue color after chilling and polishing. Metal-cutting tools should be drawn to a "straw" tint. Of course, this color may be obtained in the ordinary manner, but sometimes the person doing the tempering is in a hurry or the tool is needed quickly. In such a case the method of tempering about to be described may be employed to advantage.

### QUICK METHOD OF TEMPERING

It is applicable only to oil tempering and for best results fish oil should be used. The sequence of operations is as follows: Heat the tool to the usual cherry red and plunge in the oil. Next return the tool direct to the fire and heat again, watching it closely. When the oil adhering to the tool begins to burn, plunge again, but this time in clear cold water.

This method of tempering is more suitable to work of fairly thick cross-sections than to those that are drawn to thin edges, as in this latter case the edges become appreciably hotter than the body of the tool, resulting in either a hard brittle edge and a soft center or a soft edge and a brittle center.

The reason that this procedure is successful is because the burning or ignition temperature of the oil is approximately the same as that at which the blue color appears when the temper is drawn in the ordinary manner. A little practice will soon give fairly satisfactory results with steel of uniform quality or carbor content.

Another short cut or "stunt," where a medium hard but tough point or edge is desired on a tool, is to add soap to the water in which the tempering is done. The action of the soap is, of course, to make a suds, or in other words, to make a tough skin surrounding the steam bubbles which form when the heated steel is plunged in water. This performs a dual function. First, the more or less effective screen or protection of steam around the hot metal retards chilling somewhat and renders the steel softer and tougher than it would be if cooled in plain water. Second, when the end of a piece of heated steel is dipped in water there is a well defined line between the water

and the air, with the result that a flaw is liable to be "thrown into" the steel at this point. This may result in a fracture of the steel later on. Soap in the tempering water, by forming the screen of steam already alluded to, protects the steel from flaws at the surface of the water, as in this case the surface of the chilling fluid is not distinct or clearly defined.

The result is that the line between hot and cold metal is likewise indefinite. In other words, instead of having a definite line around, or rather plane extending through, the metal being tempered, on one side of which the metal is hot and on the other cold, a transition zone is introduced. Thus the metal grades gradually from hot to cold throughout an appreciable distance. This graduation in temperature is unfavorable to the formation of flaws.

## Telephone Pole Puller for Surface Work

In the accompanying sketch are shown the essential features and construction of a simple and easily constructed device for which a number of uses will be found about the mine property such as the "pulling" of telephone

### Lifts Poles and Posts out of Their Holes

It will also lift mine cars. The axle and wheels act as a movable fulcrum and the long pole furnishes the leverage. This puller can be used to lift light loads whenever it is possible to move it on its wheels to the point of application which, unfortunately, cannot always be done.

and trolley poles and fence posts, and the lifting of cars. In constructing this device discarded wagon-wheels, cast-iron pulleys or any other wheels of suitable diameter and construction may be used.

When wagon-wheels are used a piece of well-seasoned hickory or oak is used for the axle, the ends being turned down to fit the wheels and left long enough to provide for washers and cotter-pins to hold the wheels in place.

For a lever a pole of well-seasoned wood 6 in. in diameter and about 12 ft. long is provided and furnished at the lifting end with a good strong iron hook of suitable design. Several  $\frac{1}{2}$  in. holes should be drilled about 6 in. apart to provide for the adjustment of the lever to suit the work to be done. The lever is fastened to the axle by a bolt passing through one of these holes and through a hole of the same size in the axle.

In pulling poles with this device a couple of half hitches are taken around the pole with rope or chain the ends of which are fastened to the iron hook on the end of the pole.

## Problems In Underground Management

### Why Not Connect Butt with Inbye Face Heading and Speed Up Haulage?

Practice of Leaving Empties in One Entry and Taking Loads from  
Another Makes the Turn Slow and Wastes  
the Effort of the Locomotive

BY ANTHONY SHACIKOSKI  
Homer City, Pa.

COAL MINING today is a dual problem consisting of two distinct operations—the actual production of coal and its transportation from the working face to the tippie or shipping point after it has been mined. In many instances getting loads away from and empties to the face is quite as difficult a task as actual coal extraction.

In many mines, after a trip is loaded, the men must wait while the locomotive takes it away and returns with a trip of empties. Time lost in this manner sometimes runs from 30 to 50 per cent of the entire working day. In many cases also, this causes a corresponding loss in output. A suitable track layout in rooms and headings might do much to obviate this loss.

#### SERVING HEADINGS IN PAIRS

Fig. 1 is an imaginary mine map illustrating the track layout at present used in many mines. With the track

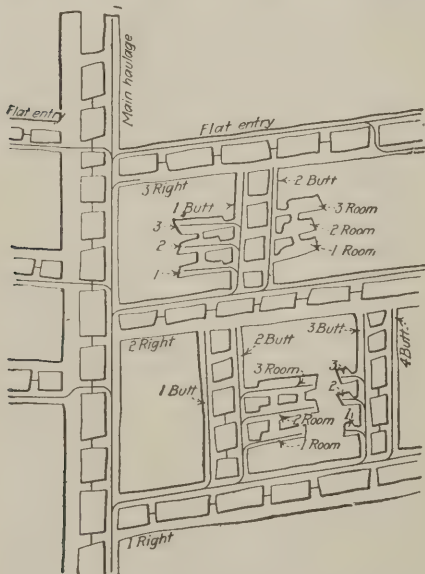

Fig. 1—Haulage System Usually Employed

This shows a portion of the map of a short wall mine and the track layout usually used. Much delay is encountered in switching loads and empties to and from the working faces.

system shown loaded cars are pulled, and the men wait until empties are brought back and placed.

The motor enters the butt entries light, pushes the loads back until the trip is complete and together. The cars are then coupled, and the locomotive pulls the trip away. If, however, there is any appreciable grade on the entry the locomotive will be unable to push the cars together, in which case they will be dropped down to the locomotive. This will cause a further loss of time.

For purposes of illustration let us assume that in No. 2 butt entry off No. 1 right there are 10 rooms with two men working in each. In order to give each man one car each trip, the locomotive must haul trips of 20 cars. Suppose also that in No. 2 butt entry off No. 2 right similar conditions prevail.

Now, in accordance with the layout, the locomotive serving these entries must either pull the cars into them and these cars must be switched into the rooms by hand in order to let the locomotive out, or the locomotive must push the cars into the rooms. If the cars are pushed and there is even a slight grade, the work of the locomotive is difficult. Again, the pushing is done against the room switches, and if these are even slightly defective more time is liable to be lost by derailments.

#### REVISED PLAN AFFORDS MOBILITY

A layout only slightly different but much more efficient is shown in Fig. 2. All butt entries are here connected at both ends with the flat entries. It is thus possible for a locomotive to enter any butt entry from either end. Accordingly, when a motor starts to make up a loaded trip and pull it from any butt entry it takes with it as many empties as it will gather loads. It enters the butt from one end pushing the loads before it and placing the empties behind it. The entry may be approached from either end and thus advantage can be taken of any grades that may exist.

Suppose that a trip is to be gathered in No. 2 butt off No. 1 right. The

locomotive comes up the main haulage road pulling the empties, turns into No. 2 right, then down No. 2 butt off No. 1 right. When the loads are reached the locomotive uncouples from the empties, gathers and pushes the loads up the butt entry. When all the loads are together the motor returns to the empties and places them. Thus the men do not have to wait any great length of time for empties as these are placed at the faces soon after the loads are withdrawn. After the empties are placed, the locomotive returns to the loads, pushes them out into No. 1 right and from there hauls them to the parting or tippie.

#### SHOULD SAVE MUCH TIME

A system of haulage such as this greatly decreases the lost motion of gathering loads and placing empties. It is estimated that it will increase the output by from 30 to 50 per cent and the output per man per day in a like proportion. This, however, depends upon conditions, that is, all considerations of grades and the like must be kept constantly in mind in laying out the trackage system above outlined.

It should be remembered that the success of any system such as this will depend largely upon the skill with which it is laid out, and how fully the designer takes into account the conditions encountered.

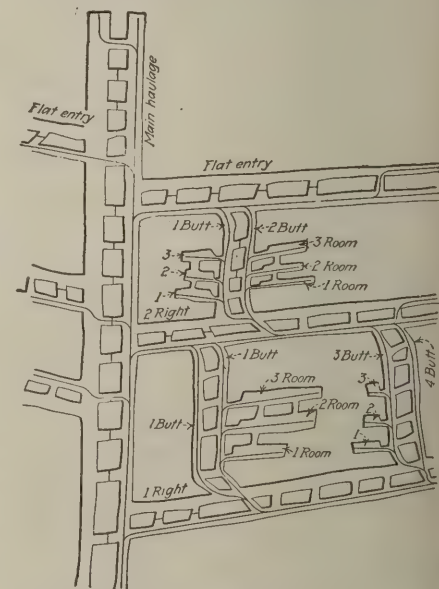

Fig. 2—Revised Mine Layout and Haulage System

Arrangement of entries and rooms is practically the same as shown in Fig. 1, but the track arrangement is such as to facilitate gathering and haulage. It is estimated that large savings can be made where this track plan is adopted.

## Discussion

### Should We Be Content with Ten per Cent Of Rock Dust in Our Mines?

Not Only Should Rock Dust Be Used in Quantity but the Workings Also Should Be Wetted Down Where Machines, Shooting of Face and Dumping of Coal Underground Make Coal Dust

THE DISCUSSIONS of safety problems, in connection with the lectures of the British safety expert, Doctor Wheeler, and the joint meeting of the several mining engineering societies and the Coal Mining Institute of America, as reported in *Coal Age* March 20 and 27 and April 3, were certainly both instructive and interesting. There are a few important statements, however, that in my opinion require further explanation; statements which, without qualification, I am sure must have mystified the average reader of *Coal Age* as they did myself.

The first statement to which I would draw attention to is this: "In the United States the mines may not have to maintain so large a percentage of incombustible matter to obtain an equal immunity (from coal-dust explosions) with that of British mines. An addition of 10 per cent of rock dust is well worth striving for." Now, what does this statement mean? Does it infer that we already have a large percentage of incombustible matter mixed with the rock dust in our mines and that an addition of only 10 per cent of rock dust is now required to give us the same immunity from dust explosions that English mines have with 50 per cent of rock dust?

Mr. Rice says, as quoted on page 463 of the issue of March 27. "The coal-dust hazard is more serious in this country than in England." Our own Bureau of Mines, experimenting on the fine dust of Pittsburgh coal, has found that a mixture containing 60 per cent of fine shale dust free from combustible matter or 60 per cent of limestone dust is necessary to prevent the ignition of the mixed dust by a blownout shot and that 75 per cent of either of these kinds of dust was required to prevent the propagation of an explosion that was once started.

This percentage would have to be maintained as a pretty general protection in nearly all the bituminous, lignite and lignitic coal districts of the United States. It seems now to be general knowledge that the explosiveness of coal dust depends, other conditions being the same, upon the ratio of the volatile matter to the total combustible matter, and Mr. Rice and Mr. Conner emphasized this point strongly in answer to Mr. Fear's question.

That being so, the Pittsburgh coal dust which has a ratio of 0.40 requires to be mixed with 60 per cent pure rock dust to be 100 per cent immune to explosion. In widely scattered sections

of the United States we find this ratio equalled and in some sections surpassed. The ratio of the volatile matter to the total combustible in coal in a few representative districts may be interesting in this connection. These are given in the accompanying table.

#### Ratio of Volatile Matter to Total Combustible in Various Bituminous Coals

Pittsburgh, Pennsylvania .....	0.40
Upper Freeport seam, Pennsylvania and Ohio .....	0.42
Hocking Valley, Ohio .....	0.42
Thacker, West Virginia .....	0.38
Vanderpod, Kentucky .....	0.38
Scott County, Tennessee .....	0.40
Jefferson County, Alabama .....	0.36
Streator, Illinois .....	0.45
Rose Hill, Iowa .....	0.49
Brazill, Indiana .....	0.41
Osage, Kansas .....	0.49
Rocky Fort, Montana .....	0.48
Rock Springs, Wyoming .....	0.40
The ratio of the lignite and lignitic coals of Wyoming, Utah, Oregon, Texas, and California range from 0.48 to 0.56.	

In view of the data in the table why should we even suggest that an addition of 10 per cent to our coal dust would serve a useful purpose when we know well that 60 per cent is necessary? Would it not be better to boost for 100 per cent protection for our lives and property than to run the risk of the partial protection that 10 per cent of rock dust might give?

With reference to the advantage gained by the use of 10 per cent of rock dust in the dust mixture which is said to give a flame traveling at 425 ft. per minute, I may say that I presume I should be as dead after being caught in such a flame as if it were traveling at a higher velocity, and in any case the afterdamp would be, to say the least, embarrassing.

The second statement I have in mind relates to the economic comparison between the different systems of humidification and rock dusting. Now how can rock dusting be compared with the different systems of humidification for the purpose of selection when all of the authorities in the discussions contend that water should continue to be used in connection with the application of rock dust?

Doctor Wheeler admits that he would like to see a limited quantity of water added with the rock dust, and Mr. Rice says that water should continue in use, for thereby the air currents will be prevented from carrying coal dust. He refers to the fact that cutting machines in Alabama are equipped with spraying devices. To supplement my argument that a combination of watering and rock dusting is considered

essential to safety, I would instance the Utah State Industrial Commission which has adopted a safety code requiring among other safety measures: Rock dusting in all mines, use of water for cutting and loading machines, sprinkling at every face, etc. So that in a great many cases where rock dusting is established in the future it will not be a reduction but an increase in safety expense.

I do not wish for a minute to give the impression that I am opposing rock dusting, but I think it is better to know what conditions we have to meet before we rush into the use of any single dust explosion preventive, to learn later that water is also necessary. Undoubtedly water is needed as a dust preventive in machine mining and where rotary or any type of dump is used inside a mine. In my opinion, the first line of defense is water on the machines in machine mining.

JOHN WALLS, SR.

Bayview, Ensley, Ala.

### Leave Four Inches of Bottom Coal to Support Machine

In regard to the "Difficult Problem" proposed by a West Virginia operator on page 22 of the issue of *Coal Age*, July 3, I would suggest cutting within the upper 48-in. body just high enough that the underlying coal would have sufficient strength to support the machine. Possibly a very thin "scrapping" will do this. Perhaps it need not be any thicker than 4 or 5 in. This scrapping should always be left one cut back of the face to hold the machine at the proper elevation for a second cutting and to permit of the shoveling being done free of the top of the soft slate below it.

E. A. SMITH,

Chief Engineer.

Wells-Elkhorn Coal Co.,  
Estill, Ky.

### Makes His Cut in Soft Slate

Our solution of the "Difficult Problem" propounded on page 22 of the present volume of *Coal Age* is, of course, tentative because it is impossible to describe all the conditions so clearly that a definite plan of operation can be made without a physical investigation, and this the writer seemed to realize for the details he supplies are scant.

We suggest that he try cutting the band of soft slate which is 4½ in. thick, amply thick to accommodate the average cutter bar of standard shortwall mining machines. This method of mining would allow the machine to rest on the 4½-in. band of coal which it is presumed is not like the coal in the main seam, so weak that it will not support the machine without skids, but if they are needed they could be used. An attempt should be made to use only chisel bits in cutting the coal as by this means the kerf will be better cleaned. This much would have to be removed as fast as it accumulated. It should be shoveled back into the gob. A long straight-handled shovel could be used to remove the muck from under the coal before it is drilled and shot down. If the machine did not work satisfac-

#### Method of Working Coal with a Soft Slate Floor

Coal is undercut in soft slate using chisel bits which clean out the cut effectually, the machine resting on the solid coal below the slate. The thin coal and rash is gobbed or loaded out and the thicker coal below it is "pop-shotted" and sent to the tippie.

torily with only chisel bits in the cutting-chain, they could be used in large proportion or perhaps in every other position along the chain. By thus cutting in the shale practically all of the 48 in. of good coal could be saved. Even if the machine cut up into the bed of coal above or into the band of coal below little if any damage would be done.

It is not clear from the information given whether the operator intends to mine the 11 in. of coal, but if it is to be saved we presume the 4½ in. coal and the 5½ in. of slaty coal will be stripped and gobbed and perhaps some of it loaded out as waste. We would suggest that this be tried and that the labor costs be carefully balanced to ascertain if the mining of this coal would

be profitable. It might pay in some localities and not in others. Of course the 48-in. coal would be cut, shot and loaded before any attempt was made to remove the lower coal because with this arrangement the coal floor can be used to shovel on. The diagram shows the track on the sandstone bottom. If the 11-in. band is saved it probably can be lifted by light "pop shots." If it is not saved the coal and slate probably will support the room track and machine. This would have to be determined by experience. In entries this method of removing the bottom seam would leave little if any top to be taken.

A. L. PLAN,  
GRADY H. EMERSON.

Birmingham, Ala.

#### Does Water Add to Violence Of Dust Explosions?

Some years ago a paper on the rates of explosions in gases was prepared by Professor H. B. Dixon, then of Manchester College, England, who was a noted authority on explosives. This was contributed to the North of England Institute of Mining Engineers. In this paper he epitomized the results of a long series of experiments proving how much moisture it was necessary to add to various explosive gases and air in order to make them exert their maximum destructive velocity and force.

He proved that it was necessary to add no less than 5 per cent of moisture per cubic foot of air and that as this heavy content of moisture could not be mixed with air by any of the usual means of dampening it he would be compelled to use steam. Incidentally, therefore, he proved that in coal mines where explosives were in use the dampening of the mine air could not possibly exert any restraining influence on the flame of the explosive, but would, on the contrary, tend to increase its force.

This important paper does not appear to have caused any notable discussion among the members of the Institute, and the facts as stated appear to have been accepted as incontrovertible and as leaving no loophole for discussion.

In view of the great emphasis that has been laid on the watering of coal mines during recent years, and still is laid on it, this becomes a remarkable

fact not easily explained. But it will be noted that when the British Government concluded its report on the "Prevention of Explosions from Coal-dust," it had no alternative but water in some form to suggest as a remedy, and therefore it became a question of the quantity of water to be used, which practically led to great laxity in the way the law was enforced. In deep collieries there was another material reason for not using large quantities of water, namely, that for the comfort and efficiency of the miners the ventilating air current should be kept as dry as possible in order to carry off the perspiration from their bodies and give them a sense of coolness.

Where it was practicable to observe the law strictly, it was observed but without favorable result. For instance, after the Clydach Vale explosion it was found that the haulage roads had been saturated with water, yet it had not exercised any controlling influence on the explosion.

The use of water sprays, dampening and steam, however, has been continued on the American continent until the present day, and has been considered the preferable method of preventing explosions. The Castlegate disaster awakened the mining public to a sense of the inability of water alone as a cure. The Utah Commission advocated the use of local watering with stone dust, distributed in the roadways and airways of the mine.

Engineers are now firmly of opinion that if the new regulations requiring rock dust are enforced with the use of only permitted explosives and electric

safety lamps, the recent explosions in coal mines will not recur, and thus my long effort to point out the uselessness of water as a preventive of colliery explosions, which commence about the year 1902 in *Mines and Minerals*, when H. H. Stoek was editor, has now found its reward and recognition.

JAMES ASHWORTH.

St. Augustine, Fla.

#### Longwall Perhaps but Why Day Men with Picks?

In answering the question of West Virginia operator in the issue of *Coal Age*, July 3, Mr. Barlow suggests that the soft slate be cut out by day-wage men and by picks. I wonder why he suggests this work should be done by hand? If it can be cut by picks it surely can be cut by machine and with greater speed. The modern shortwall machine is so arranged that the feed can be adjusted to meet varied cutting conditions.

In many coal fields slaty partings are being cut out. In one mine I recall a 7-in. streak being cut out in that way. After the slaty streak was removed the loader shoveled the slate back into the gob so that the floor was clean when the shot was fired. This slate would loosen from the coal. If the machine did not bring out all its cuttings a long-handled shovel was used to clean up the loose slate. A practically clean coal was produced.

#### DIFFICULT TO GET SUCH MEN

Just imagine hiring day men to put in a cut under a face 100 or 150 ft. wide, with some of the undercut slaty. Few miners would want the job, even if the regular day wage scale were paid for the cutting. A machine would do the work, cheaper, quicker and better. If used, the bottom should be left for a length of two cuts so that the machine could be loaded and unloaded without difficulty. The longwall might work, but the hand picks never.

Where hard labor is required in a standard operation payment should be by the work performed or the work will be done in a dilatory manner. The job of cutting out an undercut on a longwall face is a standard operation of that kind, and the work is hard. It would be a mistake to do it by day men but why do it by hard labor with machines available? Today men insist either in having a machine or powder do the work. Undercutting is nearly a dead art.

J. H. BLAIR.

Moundsville, Pa.

#### Why Glycerine Is Used for Tempering Steel

Glycerine and its water solutions, as well as oil-water emulsions, have been examined by the U. S. Bureau of Standards to find quenching media to span the gap between water and oil. From experimental quenching curves giving the rate of cooling at the center of a 1-in. cylinder of 32 per cent nickel steel, it was found that glycerine-water solutions accomplish this purpose effectively and that, moreover, they have characteristics distinctive from those of oil and apparently in their favor.

# Production And the Market

## Mathematics of Anthracite- and Bituminous-Coal Market Convincing But Demand Is Nil

Coal men have proved to their own satisfaction a hundred times that the contracts must begin soon to roll in. At first they set July as the time, and then August, now it is September, but the buyer has been amazingly reluctant. He listens to no one. He has abounding faith in the power of the mines to produce and in the railroads to haul all the coal he needs when he needs it. And just now he wants to reduce his inventories, so he is waiting. Sales are small and for prompt delivery. But the game of procrastination cannot continue much longer without the consumer being pinched. Even now the railroads are questioning their ability to handle the coal that will be needed just when equipment is in insistent demand.

The undertone of the market is good. In Arkansas the regular retail increase of 50c. a ton was made August 1, despite slack business. One operating company in Utah made a similar increase. In Alabama domestic sizes were raised 20c. a ton. The company and some independent anthracite-producers raised their schedules on an average 10c. a ton. Evidently these increases were anticipatory of a better market, of which at present hardly a shadow can be seen. The mathematics of the market is convincing, but demand is nil.

The railroads know the condition better than other consumers. They recognize their inability to meet the situation, but the consideration that has been shown them has convinced them that no matter what happens they will be allowed to take care of themselves. Why should they take a place at the distributing window when they know that they can at any time force their way to the front when the line begins "to form on the right," and so far it has not even begun to form.

Coal Age Index of spot prices of bituminous coal showed no change during the past week, standing on August 4 at 163, the corresponding price being \$1.98.

Hampton Roads dumpings for all accounts during the

week ended July 31, totaled 352,000 net tons, an increase of 8,940 tons from the week preceding but the tonnage failed to reach that of the week ending July 17, when 373,600 net tons were handled. The movement of coal at the Lakes made a further advance, being for the week ending Aug. 3, according to the Ore and Coal Exchange: For cargo 830,915 net tons and for fuel 44,066 net tons as against totals of 785,317 and 43,443 net tons respectively the week before.

The production of bituminous coal for the fourth week of July improved slightly, the output according to the Geological Survey totalling 7,564,000 tons, an

activity that has not been exceeded since March 29 of this year. The previous week showed an output of 7,401,000, according to the revised figures. Anthracite production decreased, being 1,837,000 net tons in the week ending July 26 and 1,840,000 in the previous week.

Anthracite shows a stagnation closely paralleling that of bituminous. The Canadian retailers have large stocks of it which no one seems anxious to buy. Buffalo is proposing to use bituminous in place of anthracite to heat its public schools. The combined effect of dilatory buying and substitution threatens to put anthracite operation on slow time.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

(a) Revised from last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Recovers Slowly

It is still difficult for the Midwest coal trade to feel the market rebound. There is a distinct pick-up in inquiry and without doubt buying is getting a little stronger every week, but there is nothing even faintly resembling a rush for any grade of coal. Steam coals from the principal Illinois and Indiana fields are in slightly better demand but that doesn't mean much, for storage piles are still supplying most wants except for those railroads and industrials which made short-time contracts during the summer at ridiculously low prices. Strip pits are busy on steam business. Deep mines must give their coal away to place any tonnage.

Illinois and Indiana mine running time was increased by a narrow percentage during the past week due to the slight domestic betterment. However this very increase had a tendency to further demoralize quotations. It is hard work for the strongest operators to maintain prices in the face of the cutting that goes on regularly.

In the Duquoin and Jackson County fields of Illinois conditions are much the same as in the Cartersville district, with practically nothing doing and no market and no prices. In the Mt. Olive district things are practically at a standstill excepting mines working on contracts and railroad coal.

The Standard district still continues to lag. There is no demand for any kind of coal and all sizes remain on track unbilled. The problem of the future is the steam market. With the mines working scarcely two days a week there is an overproduction of steam sizes. When the domestic demand gets good the disposal of the steam coal will worry the operator.

### Kentucky Feels Encouraged a Little

Louisville coal men report that July business closed somewhat more active than June business. The outlook is more promising, as the demand for domestic sizes is steadier and will improve after the vacation season ends. Utilities and steam consumers also are taking a little more fuel for immediate use and may start stocking a little coal shortly. Railroads also have been placing more coal in storage. Lake movement from eastern Kentucky has been improving a trifle.

Generally speaking utility consumption has been off, as longer days have cut down consumption of current, and some of the smaller industries have been running slow reducing their consumption of power. Street-car companies in some cities have been having light travel and have reduced their running schedules.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	Aug. 4	July 28	July 21	Aug. 6
Index .....	163	163	163	195
Weighted average price .....	\$1.98	\$1.98	\$1.98	\$2.36

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Prices continue steady on all sizes and grades, even screenings holding firmly, whereas it had been expected that some breaks would show, as a result of the Lake movement of prepared coal and increased general movement of domestic sizes. Collections are a little slow but somewhat better than they were.

Production in western Kentucky shows small increase, a few of the mines that were strike-bound having resumed operation under non-union agreements, and the demand for coal having slightly increased. However, there has been some slight trouble reported around the non-union mines, where radicals have been endeavoring to scare off negro and other labor, through intimidation. Recent visits of International President John L. Lewis and of miners from Indiana and Illinois, have put fresh "pep" into the radicals of western Kentucky.

The district, is stirred up, and production of the non-union mines cannot be heavy under such conditions. Prices are firm, with the exception of mine run, which has been showing a slight weakness.

### Northwest Buys Slowly

Movement to the docks from lower lake ports continues to improve, and forty-one cargoes were landed last week of which seven were hard coal. There are twenty-four cargoes on the way of which eight are reported as anthracite. It looks as if the docks will get as much as they want before freeze up, although an early winter is predicted.

Present indications are that the docks will take practically the same quantity of coal as last year—that is

1,400,000 tons of anthracite and nine or ten million tons of soft coal. This will supply the needs of the northwest. The difficulty will be to find storage for the coal, as the docks are well crowded at present for this time of year, and the buying movement has not as yet materialized.

Extreme dullness still pervades the Milwaukee coal market. Dealers in the interior are beginning to evince some interest in future supplies, and there is a dribble of deliveries to private consumers, but the volume of the sales is small. Anthracite was advanced 10c. per ton on Aug. 1, but prices of other grades of coal remain unchanged. Arrivals of coal by Lake are quite brisk, but receipts are far behind those of last year. Coal receipts of anthracite to date aggregate 386,538 tons, and the soft coal 960,708 tons. Last year at this time the record was 444,572 tons of anthracite, and 1,509,946 tons of soft coal.

### West Feels Temporary Flurry

Little summer storage has been reported through the Southwest. The advances of 50c. in the retail price of Arkansas semi-anthracite July 1 and Aug. 1 stimulated the demand from householders a few days before the announced increases became effective, with a corresponding increase of mail orders for operators and jobbers. But the market quickly returned to virtually its former monotonous level.

Arkansas semi-anthracite lump is now listed at \$6@\$7 a ton; semi-anthracite mine run, \$3.50@\$4; screenings, \$2. No change has yet been made in the price of Kansas coal, although one is imminent. Kansas lump still is quoted at \$4.50, nut at \$4, mine run at \$3.50 and screenings at \$2.50. Henryetta (Okla.) coal is quoted at \$4.50 for lump, \$4 for nut, \$3.25@\$3.50 for mine run and \$2 for screenings.

A slight stimulation was noted in the Colorado coal market during the week inasmuch as the average working time of the mines picked up to 20 hours. This, however, is still far from encouraging but the operators expect to be fairly busy as soon as the farmers begin to realize from their crops. Prices remain unchanged.

Business in Utah is brisk. Storage orders are coming in in good volume since the increase in prices a few weeks ago. Lump is in greatest demand, but other sizes also are selling. Production is up to a little more than 40 per cent now and increasing. One operating company raised its prices 50c. a ton on Aug. 1, and a general increase is expected not later than Sept. 1.

### Cincinnati Seents Better Trade

More optimism but no advances in price summarizes market conditions in Cincinnati during the week past. Better inquiry from domestic coal buyers in Indiana and northern Ohio has followed the rise in the price of grains. Lake buyers are now nearly 4,000,000 tons short of the normal movement. These two factors soon must move this sluggish market to action. Nevertheless the mines are loading less coal than usual as car records prove.

There is a wide divergence between the asked and sales prices. Steam slack and mine run seem to have reached rock bottom. They surely cannot be pounded below 75c. and \$1.25 respectively. On the other hand the positions of egg and 2-in. coal have been slightly bettered, the latter being the preferred size for heavy lake shipments. A number of the dealers and direct mine representatives here are turning down business where deliveries a month hence are specified. This is taken to indicate that they have high hopes of a betterment in price. Collections are slow.

While trade in Columbus is still dull, signs of improvement are discernible. Buying on the part of dealers has increased slightly and there also is a better steam trade. Consumers, however, continue to play a waiting game. Retail prices are fairly steady at the levels which have prevailed for some time. Utilities are buying fairly well, but owing to unsettled industrial conditions, consumption is not at a high point. Boards of education are asking for bids on school coal and some municipalities also are looking around. Lake trade is steady and the congestion of cars between Columbus and Toledo has been relieved. Bottoms are more plentiful.

The output in the eastern Ohio field for the week ended July 26 is approximately the same as that of the preceding week. Operators and jobbers say that more inquiries are being received. The increased production is attributable to a general demand for steam coal. One or two steel com-

panies in this vicinity having placed good-sized orders for fuel. Spot quotations on slack and nut and slack have stiffened 5 to 15c. per ton. This is due, largely, to the stronger demand for this auxiliary steam fuel and its reduction in quantity. Less fuel is being loaded for the lakes so less slack remains to be disposed of.

Coal production in the Pittsburgh district has increased slightly in the past two or three weeks, but one searches the market in vain for evidences of any concurrent increase in sales activity. There is no demand in the district for lake coal.

Trade at Buffalo is light and promises to remain so awhile. Consumers have on the average six weeks' supply and demand will be light till conditions change.

Midsummer dullness still prevails in the Toronto market. The yards are well stocked, with shipments coming forward in moderate quantities.

### New England Market Sluggish

In New England the trade shows almost no change. Both all rail and by water the tone is extremely sluggish, and aside from scattering purchases for relatively small tonnages there is little doing in any direction. Neither in textiles nor in shoes is there any optimism over the near future, and under such conditions buyers are not likely to be much interested. Reserves of coal are reasonably large, and at the present rate of consumption it will be months before they are depleted.

Receipts by water have somewhat increased during the past week, but this is more an indication of oversupply than any favorable turn to the market. The result is a depression in prices to a point below any of the quotations of two to three months ago. Few factors now pretend to get more than \$4.25 per gross ton f.o.b. vessel at Hampton Roads, or \$5.50 on cars at Boston or Providence. There are active rumors that sales have been made under these levels, but they are not easy to verify.

All rail from central Pennsylvania there is no better outlook than a month ago. The lower range of prices on Pocahontas and New River tends naturally to restrict the area open to deliveries all rail, and even on the quality coals the tonnage moved is very light.

At the Philadelphia and New York piers the dumpings continue very small and confined to specialties. Gas-producing coal seems to be moving in fair volume, but this is staple business and is applied on contracts that call for somewhat heavier shipments at this time of year in order to begin accumulation for the winter.

### Atlantic Seaboard Dull but Hopeful

Little life is visible in the New York market. Nevertheless there are indications that the slump has about reached its end. A slightly better tone is evident, although it has not taken the form of new orders, consumers continuing to depend on reserve stocks. Receipts at the tide water piers were smaller last week, averaging between 1,200 and 1,300 cars daily. This, however, was more than sufficient to take care of current business, and bargain hunters frequently were able to get cheap cargoes.

Nothing in the Philadelphia bituminous trade encourages the belief that a better demand for coal is in sight. There is, however, growing evidence of greater industrial activity. Plants which had been working on short time are adding more hours to their week but the railroads will not buy.

The Baltimore market is dull indeed. Demand is lacking

and that is the whole story. The railroads are urging that coal be laid in now as cars and locomotives will be needed later for transportation of grain, but since the excitement of war days, when men did many things simply because they were told it was good for the country to do it, there has been a reversal of form, and even intelligent propaganda that is backed by the soundest of good sense has lost a large part of its force.

Some Birmingham interests report that there is a better undertone in the market, but no actual improvement is claimed in either inquiry or business booked. Trade is still dependent on scattering orders for small tonnage and prompt shipment. Consumers have scarcely any stocks, and they do not seem to want any. Domestic sales are at a low ebb. The retail trade is slack and contract deliveries are held up almost entirely.

### Anthracite Demand Shrinks Further

Less demand and a slight cut in quotations for many of the independent domestic coals featured the hard-coal market at New York last week. The large companies, including some of the biggest independent operators, advanced mine-price schedules for domestic coals on an average of about 10c. per ton. Stove continues to be the most sought size and commands a premium over the other sizes when taken separately. There is a fair demand for egg and chestnut, with the former a little stronger and quotations higher than for chestnut. Forced sales of chestnut bring less than current quotations. Considerable pea coal is reported in storage, quotations for the independent product going as low as \$4, except for the best grades. Steam sizes are moving under pressure. There is considerable storing in progress and many retail yards are filled to the limit.

In Philadelphia, August is living up to expectations. Retailing is extremely sluggish. It is difficult to see, how suspension of mining can be avoided. The company operators probably will store the surplus, if any, in their big yards, but this the independents cannot do.

Producers seem to have confidence that they will get through August without extraordinary difficulty, as evidenced by the fact that most of them have added 10c. a ton to their prices. Some did not increase nut, and others let stove stay, but all in some way made increases. This is true both of companies and independents. Baltimore dealers have considerable stocks on hand.

The Connellsville coke market, taken as a whole, is very quiet. Furnace coke is practically stagnant, and there is scarcely any buying in smelter coke. In heating coke and in foundry coke there is a moderate movement. Furnace coke is steady at \$3. Good-grade medium-sulphur coke is \$2.75 to \$2.85, with ordinary heating coke at \$2.60 to \$2.75, and first drawings sometimes going down to \$2.50. Foundry coke has been gradually softening for several weeks and is now definitely quotable down 25c., at a range of \$4. to \$4.50. Occasionally \$4.75 is obtained on small lots for choice brands. In the Birmingham district another furnace stack has been laid idle during the past week. Foundry coke quotations range from \$4.50 to \$5.50 per ton at ovens.

## Foreign Market And Export News

### British Market Weak Save for Best Steams; German Competition Reappears

There is practically no change to record in the Welsh coal market. Best steam coals are going a little better, but there is a considerable surplus of all other kinds. Inquiry from Europe is poor, and considerable competition is being experienced from Germany now that the Ruhr collieries are again in working order. Many of the collieries are working short time and several more of the older pits have been closed down. Miners are now offering to work on a piecework basis in some collieries to prevent shutting down. There is occasional acceptance of these offers by producers. Some operators are making heavy cuts to effect clearances, and buyers are fairly successful in "bearing" prices.

There is no improvement in the Newcastle market and German competition is playing its part here also. The domestic and industrial markets have declined a little owing to the recent spell of very warm weather and the general slackness of trade. There are no contracts to report.

Production by British collieries during the week ended July 19, according to a cable to *Coal Age*, totaled 4,904,000 tons, compared with 5,002,000 tons during the week ended July 12.

#### Hampton Roads Trade Picks Up; Prices Stiffening

Business is showing a tendency to pick up at Hampton Roads, with prospect of substantial increase around the middle or latter part of August. Dumpings for July at the piers kept well up to the average, though they were slightly below the record for the corresponding month of last year.

The tone of the market is slightly stronger, with reports of activity in the textile fields in this territory soon to bring a bigger demand.

Some distress coal is being bought in small cargoes at prices well below the market, but prices generally are stiffening.

#### Demand for Industrial Coal Shrinks in French Market

Inquiry for industrial coals in the French market has shrunk and stocks are increasing. The household coal situation is favorable, except for bituminous coals and ovoids. Disposal of industrial grades in the East and Lorraine regions is difficult owing to the stocks accumulated at the end of winter in the fear of British and German strikes and increased since by the Sarre mines through liquidation of their formidable arrears in deliveries during the winter.

In the Ruhr, coal and coke have been lowered 20 per cent in price. Nevertheless indemnity fuels are actually dearer than Belgian, British and French coals.

The Belgian market is quite weak in industrial coals and stocks at the mines

are accumulating as arrivals from the Ruhr increase. On the other hand, as the French Government is about to suppress fuel export permits, a recrudescence of French competition is expected, notably in the regions of Borinage and Tournaisis.

During the first fifteen days of July the O.R.C.A. was supplied with 218,992 tons of coke, or a daily average of 14,600 tons.

## News Items From Field and Trade

### ALABAMA

The Corona Coal Co., of Corona, is reported to be preparing to open a mine at Mount Valley that will necessitate some railroad building.

### COLORADO

The Moffatt Coal Co. is reported making preparations to open the Elkhead mine, an anthracite property on Cottonwood Creek, near Steamboat Springs.

The Colorado Fuel & Iron Co. reports a deficit of \$27,304 for the quarter ended June 30, after all charges and reserves, compared with a surplus of \$498,057, or \$1.34 per share earned on the common stock outstanding, in the corresponding quarter last year. The gross receipts for the three months totaled \$10,851,978, as against \$12,103,515 for the June, 1923, quarter.

During the month of June Colorado mines produced 565,336 tons of coal. This is a decrease of 191,221 tons as compared with the corresponding month last year. The total number of men employed in and about the mines that month was 12,417. In addition to this being a decrease under 1923 it also is the lowest June production reported since 1909 with the exception of 1921, when 547,473 tons was produced.

### ILLINOIS

Two more coal mining companies in the Peoria field have dissolved. They are the Clarke Coal & Coke Co., of which Horace Clarke was president, and the Logal Coal Co., of which W. R. Coleman was the head.

The "Never Seen" coal mine, at Matherville, which was closed following the death in the mine of George Bugos, its owner, has been reopened and put in operation.

The strike of mining machine men in Orient No. 2 mine at West Frankfort continues with no sign of a break in spite of the fact that the state union officials including Vice-President Harry Fishwick, declare the men have no case. The strike started when the new \$10.07 day wage for loading machine runners was supposed to take effect July 16. No coal has been mined in Orient No. 2 since.

Joe M. Cravens, who owns a slope mine six miles south of Herrin, was found dead with his son Claude at the bottom of the slope on July 23. It is believed they were asphyxiated, possibly by gas fumes from a gasoline engine, which they had entered to inspect.

The younger Cravens had been married three weeks and was on a visit at Herrin from his home in Freeburg.

The Mars, a large lake collier, has delivered 7,000 tons of Fairmont (W. Va.) coal at the Hussey docks, Waukegan. This is the second coal boat of the season to dock at Waukegan, the first one having brought 8,000 tons of anthracite.

The Brewerton Coal Co. announced it would reopen its mine No. 3, at Lincoln, Aug. 1. Clean-up work was started July 28. The mine was closed for the last four months. A force of 250 men will be employed. Mine No. 2 of this company, also located at Lincoln, has been operating most of the time this summer.

No definite settlement has ever been made of the affairs of the defunct Southern Gem Coal Co., which last winter failed to pay off employees at more than seven mines in southern Illinois. Receiver W. S. Wilson denies recent reports that Mine No. 1, at West Frankfort, is to soon reopen and that the Peabody Coal Co. had bought the "West" mine at West Frankfort, and would soon reopen it.

A building and loan association has been organized at Mason, the new mining town which has been laid out by the Illinois Coal Corporation. The town is located 11 miles from Mt. Vernon. The object of the association will be to assist miners and others to erect or to buy their own homes. There are now 250 houses in the town and it is hoped that one hundred more will be erected this fall. H. D. Fischer is president of the association and C. E. Anderson secretary.

The St. Louis Coke & Iron Co. will soon move its main offices from St. Louis to Chicago, according to an announcement of Wm. C. Maguire, president. The company, which is a \$20,000,000 corporation, has its main plants at Granite City, Ill., near St. Louis, and cokes southern Illinois coal almost exclusively. The offices in Chicago probably will be located in the Continental and Commercial National Bank Bldg., where a branch office has been maintained in the past, and the former main office in the Planters' Building, St. Louis, will be made into a branch office only.

George B. Spitler, Mt. Zion, acting for a committee of the stockholders of the Lovington Coal Mining Co., Lovington, has bid in the property at bankruptcy sale for \$5,000. Included in the property are fourteen acres of land and about four thousand acres of lease-

holds. The buildings of the mine are valued at between \$40,000 and \$50,000. Several claims have been filed against the property, most of which are payrolls, which will have to be adjudicated. The amount of these claims is uncertain. With the passing of the mining property of the pool of old stockholders represented by Mr. Spitler, a new corporation will be formed at once, with capital of \$100,000, and steps will be taken immediately to put the mine in operation for hoisting coal for the fall trade. The mine has a rich vein of coal from 7 to 9 ft. thick. The monthly payroll under normal conditions is about \$30,000 and from 200 to 250 men are employed.

### INDIANA

The Indiana Coal Merchants Service Bureau, of Indianapolis, has changed its principal place of business to Anderson.

The Big Ben Coal Co. of Center Point has changed its name to the Big Ben Coal & Clay Co.

### KANSAS

District 14, United Mine Workers, recently levied its first assessment against the miners who worked the first half of June, for the benefit of those who have been unemployed during the summer. Some 2,000 men, members of forty-one locals, were said by union officials to be eligible to assistance.

### KENTUCKY

It is reported that coal traffic on the Ohio River has been materially curtailed as a result of a considerable amount of river equipment going aground, principally above Cincinnati, as a result of government engineers having raised dam wickets at points around Wheeling and Pittsburg, resulting in the lower river dropping 10 ft.

### MASSACHUSETTS

The Philadelphia & Reading Coal & Iron Co.'s lease of the Mystic Wharf coal pier of the Boston & Maine R.R., at Boston, is being terminated as of Sept. 1, a contract having been let to G. P. Carver, coal-plant engineer, to remove the superstructure of the wharf for the P. & R. It has been rumored that H. N. Hartwell & Son were to take over the plant for receiving anthracite, but confirmation of the report is lacking. The plant measures 435x125 ft., has two large discharging towers and other equipment in proportion. The

P. & R. at one time stored 35,000 tons at this wharf.

## MISSOURI

A new and larger shovel will be installed before autumn by the Liberal Coal & Mining Co., which has been operating a strip mine near Liberal for two years.

## OHIO

The Clay County Coal Co., with operations at Hima, Ky., has purchased the Buchanan interests in the Furnace Gap Coal Co.'s properties and those of the Morning Glow Mining Co., all of which will be consolidated under the one management. The Clay County Coal Co. is made up largely of those associated with the Kentucky Fuel Co., of Cincinnati, of which John Hoffman and L. F. Norning are the directing heads.

The Brady-Tucker Coal Co., with offices in the Dixie Terminal, in Cincinnati, has liquidated as of Aug. 1. Heavy losses sustained through the failure of an Indiana wholesale company are given as the cause of the determination to quit business. Larry Tucker, moving spirit in the corporation since the death of Jake Brady, will devote all of his time to the management of his father-in-law's estate. J. C. Shelly will carry over the live accounts until further arrangements to this end have been completed.

## PENNSYLVANIA

Governor Gifford Pinchot has appointed John F. Bevan, of Pottsville, as a member of the Anthracite Mine Inspectors' Examining Board.

Work on the construction of a large reservoir capable of holding approximately 2,000,000 gallons of water, has been started by the Glen Alden Coal Co. at its Taylor breaker. The reservoir is to be utilized in an effort to decrease the amount of water used in the preparation of coal, by using the same water several times. Timothy Burke, Scranton contractor, is working on the project.

The Cayuga tower, coal pockets and engine house, located in North Scranton and owned by the Glen Alden Coal Co., are soon to give way to more modern mining methods. The equipment has lain idle for many months, the fresh-mined coal being handled through nearby, more modernly equipped coal preparing plants. Morris Sullivan, of Bellevue, one of the best-known contractors in the anthracite field, has been given the contract to raze the Cayuga workings. It was Mr. Sullivan who tore down the old Bellevue breaker, now the site of the Baker breaker; the Dodge breaker; the Sloan breaker, the Hampton tower and other buildings discarded by the Glen Alden company in its advance toward greater efficiency.

A committee on mining methods, machinery and power, of the Central Pennsylvania Coal Producers' Association, composed of William Wetter (chairman), Richard Peale, L. W. Householder, E. K. Davis and Andrew B. Crichton, met in the association

rooms in Altoona recently and recommended a detailed study by the association of special machinery for loading coal and laying track.

The Schuylkill Valley Coal Co. an operation near Port Carbon, in which ex-Governor Sproul is interested, is to resume soon. The mine was closed because of the default of payment of bills and has been idle for several months, but Judge Koch, of Pottsville, has entered a decree of foreclosure in favor of the bondholders, who will operate the plant again.

James Boyle, of Freeland, has leased the old Harleigh culm and debris banks of the former Madera, Hill &

Alfred Kauffmann

Newly elected president of the Link-Belt Co. under the recent scheme of reorganization. Mr. Kauffmann was named to succeed Charles Piez and, with Mr. Piez, is a member of a newly created executive committee of four members. Before his accession to the presidency Mr. Kauffmann was second vice-president of the company.

Co.'s Black Creek Coal Co. workings on the west side of the Harleigh road. The workings are now part of the operations of the Jeddo-Highland Coal Co.

Announcement is made by the officials of the Lehigh Coal & Navigation Co., that Edward Hughes, of Philadelphia, has been named controller of that concern to succeed E. M. Reynolds, deceased. Mr. Hughes, who formerly held the position of purchasing agent, is succeeded by J. R. Bennington, his assistant. F. T. Swain has been appointed assistant purchasing agent.

Mrs. Julia Sarasin, of Dupont, Pa., has tied up the Volpe colliery. Mrs. Sarasin recently purchased five lots extending 250 ft. along a main street in Dupont and including a roadway to the Volpe colliery, the only entrance. She immediately had her land fenced, which blocked the roadway. The company protested and Mrs. Sarasin suggested she would let coal trucks cross her property at the rate of \$1 each. The company is now in court seeking an injunction against the woman realtor.

Two more big strippings are to be started in Schuylkill County. One will be at Buck Run, where work has

already begun on the opening of the veins on the north side of the mountain near the Crystal Water Co.'s dam at Rohresville. Many thousands of tons of coal are expected to be removed. The Philadelphia & Reading Coal & Iron Co. is getting ready to strip on a large scale and the largest shovel ever seen in the section is being taken up the side of the Broad, or Gordon Mountain, above Heckscherville. Another shovel is expected to be placed in service at Pine Knot soon.

The mines of the Argyle Coal Co., located at Gallitzin, after being idle for three weeks, resumed operations on July 23. This concern supplies fuel to the Pennsylvania R.R. at a coaling station for engines on the Pittsburgh division.

The Lehigh division of the Lehigh Valley Coal Co., held first-aid team contests at Hazleton last week for the first time in several years, the Oneida No. 3 team winning first place. Fourteen teams took part. The Hazleton division contest was held later. A cup is contested for by the various divisions.

The River Pollution Committee of Reading has a report on the possibility of cleansing the Schuylkill River, which is little more than a sulphur creek all the way from Shamoking to Norristown due to the many mines and washeries draining into it. The committee has received authoritative data declaring that the river can be cleaned of pollution in five years if proper measures are taken and the authorities enforce them.

Central Pennsylvania coal operators are deeply interested in a hearing being conducted by the Public Service Commission in Harrisburg on the complaint of the Rainey-Wood Coke Co., which is seeking proportional freight rates on inbound bituminous coal from the Connelville field and outbound byproducts from its Swedeland plant, near Philadelphia. The gist of the request is that the rate on coal for use in byproducts be reduced about 32c. below the rate on coal for other uses. Beehive coal producers and the railroads are opposing the rate reduction. The hearing promises to be long drawn out.

On July 26 a fall of rock in the main heading of the Lamont mine of the H. C. Frick Coke Co. near Uniontown fell on the main trip as it was passing, injuring more or less seriously thirteen employees, two of whom sustained broken backs.

Every employed mine worker in District 1, United Mine Workers, must pay an assessment of 25c. a month for the support of the unemployed miners of the district as a result of a decision reached by the members of the district executive board. The assessment is effective immediately and will be continued until further notice.

A syndicate headed by McLaughlin, MacAfee & Co., of Pittsburgh, and Schibener, Boenning & Co., of Philadelphia, is offering an issue of \$1,250,000 Shamokin Coal Co. first mortgage 6½ per cent sinking-fund gold bonds, due Aug. 1, 1944, at 100 and interest, to yield 6.50 per cent. The company owns in fee simple a tract of anthra-

cite located within the borough of Shamokin and Coal township, Northumberland County. Sixteen veins of coal estimated to contain over 24,000,000 tons of virgin anthracite are located within the property. Prominent anthracite operators of New York and Philadelphia are interested in the company.

Five miners from Jerome, Somerset County, were sent to the Western Penitentiary for from 18 months to 10 years, having been convicted of dynamiting the Baltimore & Ohio R.R. bridge leading to the Hillman Coal & Coke Co. mines at Jerome during the 1922 strike in an endeavor to interrupt the operation of these mines.

## WASHINGTON

Local engineers at Bellingham have been making tests between the surface and the interior of the Bellingham mine of a radio communication system which has been worked out by W. A. Germain, a local radio expert. Mr. Germain, recently held an exhibition for the benefit of the Bellingham chapter of the American Association of Engineers.

## WEST VIRGINIA

Designating T. F. Henritze as commissioner in chancery to make an examination of the affairs of the Tarney Collieries Co. and E. C. Bralley as receiver, Judge I. C. Herndon, in the Circuit Court of McDowell County, directed a full accounting of the affairs of the company, following charges of mismanagement and juggling of funds made by George W. Lambert, wealthy coal operator and a large stockholder in the Tarney concern. Mr. Lambert asserts that he has been unable to find out just what the assets of the company are and that recently a number of judgments aggregating a large amount have been awarded against the collieries company.

The Island Creek Coal Co. reports total net profit of \$1,436,874 for the six months ended June 30, 1924, against \$1,361,230 in the corresponding period last year. After common and preferred dividends the company reported a surplus for the half year of \$574,488, against \$23,653 in 1923. The net profits for the first half of 1924, after allowing for the dividends on the preferred stock, were equal to \$10.83 a share on the 118,801 shares of common stock outstanding, against \$10.20 a share in the corresponding period last year. The net profit for the June quarter totaled \$438,643, or \$3.07 a share on the common as compared with net profit of \$622,954, or \$4.72 a share reported for the same quarter in 1923. The company produced 2,050,907 tons of coal in the six months ended June 30, 1924, against 1,278,818 tons produced in the first half of 1923.

The Tidewater Coal Inspection Bureau has been opened at Norfolk in charge of H. B. Tarrant, chief inspector, for the purpose of sampling coal in yards, cars and cargoes. Mr. Tarrant, who has been engaged in similar work at Norfolk for several years, formerly was with the U. S. Fuel

Administration. A new method of handling coal at the piers to decrease the percentage of slack and dust is being demonstrated by M. Tarrant, who asserts that he can practically guarantee 10 per cent more lump in cargoes.

## CANADA

The Toronto Wholesale Coal Dealers' Association has been adding a number of new members lately, and is arranging to resume its luncheon meetings.

Output of bituminous coal in Alberta for the first five months of 1924 was 1,133,568 tons as against 1,576,046 tons

Charles Piez

As the result of a reorganization of the administrative force of the Link-Belt Co., Mr. Piez has retired as president of the company and has been elected chairman of the board. He also has been named as chairman of a newly created executive committee of four members, who will act in an advisory capacity. He held the office of president of the organization for eighteen years and has been succeeded by Alfred Kauffmann.

for the same months of the previous year. Sub-bituminous coal production was 409,330 tons for the 1924 period as against 244,561 tons during the early part of 1923.

Production of coal in British Columbia for the month of June shows an improvement. The mines on Vancouver Island now are working almost full time. Those of the Nicola-Princeton field also are feeling the effects of the improved trade. The Crows Nest Pass Collieries are idle because of the strike.

Roy Wolvin, president of the British Empire Steel Corporation and other officials recently made a visit of inspection to the Picton County plants of the company. After conferring with T. J. Brown, Deputy Minister of Mines, it was decided not to reopen the Allan mine, in which the recent explosion occurred, until at least the end of August.

The Dominion Coal Co. has made a general cut in the pay of all officials, affecting all salaried men from President Wolvin down to the lowest paid clerk. The cut in the pay of the highest salaried officers is 25 per cent, the reduction in the case of the smaller

salaries being 10 per cent, and between the two extremes the reductions are proportionate to the salaries paid.

## New Companies

The Goldville Mining Co., a coal company, has been incorporated in Spiro, Okla., with a capital stock of \$60,000, by R. L. Redwine, J. R. Redwine and J. S. Sorells.

The Old Cato Coal Mining Co. has been incorporated in Henryetta, Okla., with a capital stock of \$25,000, by C. E. Downs and Ben Meyers, both of Los Angeles, Cal., and G. L. Smith, of Henryetta.

The Blue Goose Coal Co. has been incorporated in Knoxville, Tenn., with a capital stock of \$75,000, by C. L. Peterson, L. A. Bible and C. A. Bowen.

A charter has been issued to the Anthracite Fuel Corporation, of Wilkes-Barre, Pa. It has a capital stock of \$15,000, and Ralph P. Thomas, 18 East Pettebone Street, Forty-Fort, is treasurer. The incorporators are: Treasurer Thomas, Walter W. Harris, Scranton, and James P. Harris, Kingston, Pa.

The Normandale Coal Co. has been formed to take over the Normandale property, two miles from Nicola, B. C., on which a 12-ft. seam of good bituminous coal has been opened. The property will be developed under Edward Floyd, managing director of the company, who has had wide experience in the Newcastle fields, England, and the Westville fields, Nova Scotia.

The Dick Coal Co. has been organized to mine coal in Lewis County, West Virginia. The company is capitalized at \$25,000 and will have its principal office at Weston. Interested in the new concern are Charles P. Darlington, J. W. Marsh, J. W. Eakin, J. E. Griffin and P. D. Marsh, all of Weston.

The Alma Pond Creek Coal Co. has been organized to operate in the Thacker field of West Virginia. The company is capitalized at \$150,000. It is to operate near Sprigg, W. Va. Among those active in organizing the new company were H. L. Ducker, R. C. Pforr, P. P. Gibson, D. G. Hughes and M. F. Breslin, all of Huntington, W. Va.

The following bituminous-coal companies were recently incorporated at Harrisburg, Pa.: Viaduct Coal Co., Summerville, Pa.; capital, \$10,000; incorporators, I. W. Carrier, Baxter, treasurer; H. L. Carrier, Summerville, and H. A. Corbett, Summerville. Campudas Coal Co., Carnegie, Pa., capital, \$50,000; incorporators, Charles H. Campman, Seventh St., and Doolittle Avenue, Carnegie, treasurer; John Tudas, Carnegie, and S. E. Wentley, West Elizabeth, beth.

## Publications Received

**Pumps, Centrifugal.** The De Laval Steam Turbine Co., of Trenton, N. J., has just issued a new booklet on single-stage and multi-stage centrifugal pumps. This booklet covers manufacturing methods and materials, testing, and pump details. Other sections are devoted to speed reducing gears, drives, pump applications, characteristics and engineering data.

**Efficiencies in the Use of Bituminous Coking Coal as Water-Gas Generator Fuel.** by W. W. Odell, Bureau of Mines, Washington, D. C. Technical Paper 274. Pp. 39; 6x9 in.; illustrated. This paper is one of a series of publications dealing with an investigation relating to the manufacture of water gas. This investigation was conducted under a co-operative agreement between the Bureau of Mines, Department of the Interior, State Geological Division of Illinois and the Engineering Experiment Station of the University of Illinois.

**Shape Book** (9th edition), published by the Carnegie Steel Co., is now off the press and available to users of steel. The new edition is the result of a thorough check and revision of all the sections rolled by Carnegie Steel Co. on its shape, rail, bar and plate mills, and though no important changes have been made in the regular sizes of structural and bar-mill sizes of beams, channels, angles, tees and zees, a number have been made in the large number of special sections rolled by that company, such as concrete reinforcement bars, window and casement sections, automobile rim sections and other miscellaneous bar-mill sections.

## Traffic News

### Roads May Appeal to High Court Against Indiana Rate Cut

As a result of the ruling of Federal Judge Alschuler, with that of Judges Wilkerson and Carpenter, of Chicago, in denying an injunction to the Baltimore & Ohio and other railroads which sought to restrain the Indiana Public Service Commission from reducing coal freight rates within the State of Indiana, the roads may appeal their case to the Supreme Court, according to unofficial statements of officials of the coal-carrying roads of Indiana.

The ruling of the federal court means that beginning Aug. 1, coal shipped from Indiana mines to points within the state will benefit by a carrier rate from 5 to 28c. lower.

The railroad companies sought to obtain a temporary restraining order pending a decision of the Indiana Supreme Court on a permanent injunction.

### Producers Prepare to Fight Lower Rates Into Indiana

Indiana coal operators are preparing for their fight against reduction of freight rates on coal from Ohio, West Virginia and Kentucky fields to points in Indiana. This follows the filing of the petition by R. B. Capstick, traffic manager of the Indiana State Chamber of Commerce, with the Interstate Commerce Commission against 56 railroads, comprising the Central Freight Association. At the same time the Chamber of Commerce of Terre Haute sent a protest against the state chamber explaining that such a petition was unfair because it would hurt not only Terre Haute but all parts of the state in which coal mining was a main industry.

The hearing on the petition will be held in Indianapolis early in September.

### Commerce Commission to Expedite Lake Cargo Coal Case

In an effort to expedite the Lake cargo coal case, the abstracts of evidence are to be filed Aug. 18, in advance of the argumental portion of the briefs, which are to be in the hands of the Interstate Commerce Commission Sept. 15. Since the chances are that there will be exceptions to the tentative report, time must be allowed for final oral argument. It is known that the commission is anxious to render its decision as early as possible so as not to delay negotiations for coal to move by way of the lakes on the opening of navigation next spring.

### Coal-Rate Hearings Announced

The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, will hold a hearing in Room 606, Chamber of Commerce Building, Pittsburgh, Pa., Thursday, Aug. 14, at 10 a.m., daylight saving time, on a proposal to change the rate on bituminous coal, carloads, to 76c. per net ton from Coaldale Mine and Mineral Siding on the B. & O. R.R. in the Cambridge

(Ohio) district to the following stations in Ohio: Lore City, Cambridge, Cassell, New Concord, Sundale, Bridgeville and Sonora. At the time the rate, of which the present 68c. rate is the outgrowth, was first established to Cambridge, there were no mines on the Baltimore & Ohio in the Cambridge district west of Cambridge, and it was the intention to limit the reduced rate to mines between Lore City and Cambridge. Through oversight when mines were opened west of Cambridge, the reduced basis was extended to all main-line mines in the Cambridge district. It is desired now to correct this situation.

A hearing also will be held at the same time and place on the following proposed change in the rate on coke, except byproduct coke, carloads, from ovens in Chesapeake & Ohio Ry. districts to Niagara Falls, Ont.: Rate of \$5.01 per net ton to be cancelled, leaving through rates to be made on the sums of locals via Detroit. This is proposed to meet the demand of Canadian lines for cancellation of all joint through rates on coke from United States points to destinations in Canada that represent the through charge less than that available, under the combination of local or proportional rates, and from the national boundary via which handled.

Proposed increases in the rates on coal in carload lots from certain stations in Oklahoma to various Southwestern States have been ordered suspended by the Interstate Commerce Commission until Nov. 25.

## Obituary

John H. Dunlap, secretary of the American Society of Civil Engineers, died July 29 as a result of injuries received in a railroad wreck a month ago, when he was returning with some other engineering professors from the meeting of the Society for the Promotion of Engineering Education at Boulder, Col. President McNair of the Michigan School of Mines and Professor Ives of Ohio State University, also were killed in this wreck.

## Coming Meetings

**Rocky Mountain Coal Mining Institute.** Summer meeting, Aug. 7-9, Rock Springs, Wyo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

**New York State Coal Merchants Association, Inc.** 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters, Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

**American Chemical Society.** Fall convention Sept. 8-11, 1924, at Ithaca, N. Y. Secretary Gas and Fuel Section, O. O. Malleis, the Koppers Co., Pittsburgh, Pa.

**Oklahoma Coal Operators' Association.** Annual meeting Sept. 11, 1924, McAlester, Okla. Secretary, A. C. Casey, McAlester, Okla.

**Association of Iron and Steel Electrical Engineers.** Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Miner's Lamp Made of Aluminum

A new acetylene miner's lamp is made of cast aluminum, with walls  $\frac{1}{8}$  in. thick and seamless. The water tank and carbide cup are ribbed, as may be seen in the accompanying illustration. This feature adds strength and permits a firm grip for unscrewing the cup. Construction is simple and

### Of Light Weight But Durable

Corrugations in carbide and water container stiffen these parts and make both stronger than the nature of the metal would suggest.

the lamp can be taken completely apart and put together again in a few minutes. Every part in it is replaceable. In spite of its solid metal walls and great strength, it weighs less than brass lamps of the same size. The new lamp is made by the Fred R. Belt Co., Inc., 355-361 W. Ontario St., Chicago, Ill. It is named the "Lu-mi-num" lamp.

### Continuous-Tread Shovel Has Broad Operating Base

Continuous tread equipment has been adapted by the Osgood Co., Marion, Ohio, to its standard shovels, supplementing the railroad truck and traction mountings. Continuous-tread mountings which are made for shovels of dipper capacities ranging from 1½ to 6-cu.yd., can be easily put on in the field to replace other mountings and are readily removed when it is necessary to ship the shovel by rail.

With the new continuous-tread mounting the track and accessories are eliminated and the pit crew dispensed with or greatly reduced; the shovel can be kept in the most effective digging position, can back away from blasting and can travel and work in water; and the location of the shovel can be changed in minimum time.

These results are obtainable with either heavy traction or continuous-tread mounting. The main difference in

### Continuous Tread Shovel

For relatively soft ground. To steer the shovel a transverse screw with a traveling nut slews the rear truck. The screw is operated by a small engine near the boiler firebox.

the two is in the nature of the ground that each can negotiate. The traction wheels are most successful on hard bottoms, have greater simplicity and are lower in cost. The continuous-tread mounting, at somewhat greater cost, enables the shovel to travel and work on a comparatively broken, faulted and moderately soft surface.

### BELT TREADS REPLACE SIDE JACKS

The mounting consists of two continuous-tread belt units carried on side brackets, replacing the jack arms at the forward end of the machine, and a narrow, double-belt truck occupying the same position as the rear railroad truck. The side brackets are somewhat similar in shape to the jack arms used with the railroad mounting and occupy the same position but are much heavier. They are rigidly attached and braced.

The front tread-belt units are mounted on journals at the outer ends of the jack arms and can rock to accommodate themselves to uneven ground surfaces. The rear truck furnishes a third point of support for the shovel and has a universal action so as to rest firmly on uneven surfaces. To steer the shovel the rear truck is slewed by means of a transverse screw shaft carrying a traveling nut.

The shovel is propelled through the front units only or through both front and rear trucks by power derived from the hoisting engines. The tractive effort is suitably increased by a series of heavy cast-steel spur gears with teeth cut from the solid. These gears with their shafts are assembled in a sub-frame which can be put on or removed as a unit.

### PROVISIONS MADE FOR ROCKING

From the ends of the forward shaft in the sub-frame the power is continued out to each front unit by a universal jointed propeller shaft. As the continuous-tread units are free to rock, these shafts must be provided with means to enable them to work at varying angles.

Power for steering is provided by a small double reversible engine mounted on the deck beside the boiler firebox. The drive from engine to steering screw is direct and without shafts, bevel gears or clutches. The spread of the mounting at the front is approximately the same as the jack screw spread on the railroad mounting. This, with the weight of the forward units, makes the shovel stable under all conditions.

## Light Electric Hoists Pull Cars and Scrape Coal

Single-drum and double-drum electric portable hoists have been designed by the Sullivan Machinery Co. and are now in successful use in different parts of the country.

As in the air hoist, the motor of the electric machine is contained entirely within the drum, a fact which makes for compactness, simplicity and ease of handling.

In the single-drum hoist, the motor is supported at one end of the frame or base, and supplies power, through reduction gears to the hoisting drum, which is of 11½ in. diameter and 8¼ in. long. This relatively large drum diameter reduces strain and wear on the hoisting rope, which is a ⅝-in. wire cable. The drum holds 500 ft. of rope.

The horsepower and rating of the hoists are similar to those of the compressed-air machine, namely: 6½ hp. with a capacity of 2,000 lb. dead load vertically, at a speed of 110 ft. per minute on single lines. When hauling cars, for example, on moderate grades

or on the level, the pulling power is much greater. The accompanying curve sheet shows the ability of the hoist in this direction, and applies to both the single- and double-drum machines.

For example, the Steubenville Coal & Mining Co., Steubenville, Ohio, which is using one of the single-drum hoists to pull trips of loaded cars into the bottom as a relief measure for the haulage motor, reports that trips of forty cars with a gross weight of 96,000 lb. are handled satisfactorily. The grade averaged about 1½ per cent and was on a slight curve. In this case the hoist was bolted to timbers between the tracks, but the location or position of the hoist has no effect on its operation. It may be mounted on a crossbar or column in a shaft handling timbers; bolted to a timber or a girder, or to a tree, or to a wall or floor, for pulling cars, piling timber, or odd jobs of

### Single-Drum Hoist for Pulling in One Direction Only

Used at Steubenville to pull trips of forty loaded cars weighing 48 tons into shaft bottom.

hoisting and hauling. The single-drum hoist weighs 480 lb. The double-drum can be used also for pulling a coal scraper instead of a hoist on a foundation. This machine weighs 770 lb., is 38 in. long by 15 in. wide, and stands 19 in. high.

In the double-drum-hoist the electric motor is mounted between the two drums on a central standard, carrying a pinion at each end of its armature shaft, and thus furnishing power through reduction gears, to the two drums, each of which is 11½ in. in diameter by 6¼ in. in length, with a capacity of 250 ft. each of ⅝ in. wire rope. The right-hand or haulage drum has an operating speed at full load (2,000 lb. vertical lift) of 110 ft. per minute. The gearing of the left hand or tail rope drum provides for 160 ft. per minute for handling the empty scraper.

The 6½-hp. motor, built especially for this hoist draws about 25 amp. when running the hoist at full capacity. It is a compound-wound motor. It is totally inclosed, so that dust and dirt are excluded. The temperature rating is ten minutes full load, with a 55-deg. centigrade rise. The motor will run continuously at no load without overheating. The above ten-minute period, of course, is longer than any during which the hoist will be called upon to deliver its full-load rating under any ordinary conditions. This machine is constructed with compound windings.

### Capacity of Single- or Double-Drum Hoist

For heavy inclinations use the larger, lower, left-hand graph. For lighter grades use the graph in the upper right-hand corner. Thus the hoist will pull 20 tons on a level track.

## Wanted: A Leader

**C**ONSUMERS are in great need of safe leadership, some outstanding coal purchaser who by his timely purchases and abstentions from the market will prevent hit-and-miss buying. The railroad companies now are the real leaders. When the Pennsylvania R.R. starts to buy and stock coal the word goes around and industry buys. But the leadership of the railroads is not safe. It is liable to bring industry into trouble. The railroads have power to get coal and get it at a low price which is not vouchsafed to the ordinary buyer. The purchasing agent of the railroad does not need to be so circumspect as he does in other industries. He can afford to wait a little longer.

The United States Steel Corporation might serve as such a leader did it not have its own mines. In consequence of that ownership, its action always is believed to have reference to its own internal policy, its own capacities of production and not to the main problems of a possible general shortage of coal. Many other industries including the railroads have their own mines, so the smaller manufacturer has no leading industry to dictate his policy. Were there such an industrial leader who could appoint agents to ascertain the facts and direct his action, we might find the public better apprized. As it is no one seems able to lead, the Department of Commerce, the U. S. Geological Survey, the members of the defunct U. S. Coal Commission, the American Engineering Council, the National Coal Association or the United Mine Workers of America, because they merely advise, and industry has to expend money when it follows their advice. When a coal consumer buys he puts money back of his judgment. And money talks.

## Rock Dusting

**N**O EXCUSE will serve for those who are found next winter with their mines unprotected by rock dust. Those operators who have mine explosions in the coming cold season will have a difficult time reconciling their consciences and satisfying the mining departments and the public. Coal men are always deprecating the multitude of statutes passed for their direction and admonishment. Here is a chance to prove that the industry follows the higher law and does not wait for legislative action.

The insurance companies are doing their part. What is the industry doing? Certainly not as much as needs to be done and done quickly. When the laws are passed let them come into effect promptly, for rock dusting has been proved almost as cheap as it is efficacious. The improvements in the mines of the Utah Fuel Co. are an instance of aggressive safety work. That company is reported as making every effort to make its ill-fated mine safe both with water as a preventive at the face and rock dust as a localizer of explosions. Its action should be an exemplar to other companies. Attack

explosions at the source and arrange to trap them if all else fails.

More rock-dusting equipment companies should enter the field. The industry needs them, but operators should not forget that equipment is not readily obtainable and so should enter the field early. They should not leave the problem till it is too late to get supplies for the protection of their mines this winter.

Do your Christmas shopping early and prove to your men that you have their safety at heart.

## You'd Be Surprised!

**A** COAL mining man can get pretty much down in the mouth these summer days if he simply sits at home and looks at the "no bills" rusting to the track down by the quiet tippie. But if he were roaming around from Bellingham to Birmingham he wouldn't feel so bad. He would continually stumble upon somebody working out the salvation of the coal industry. He would be surprised and then interested and then enthused over the vast amount of thought and ingenuity that are busily producing new devices and methods for getting out coal cheaply.

It is going on everywhere. Probably no other year in the history of coal mining has been so active in this particular. It is well known that great progress has been made in West Virginia in the loading out of coal by conveyor. Devices for both cutting and loading coal are developing there, thanks to the absence of Mr. Lewis' benign influence. Something has been said about a good many of them. But there are developments elsewhere, too, though the developers of necessity are keeping their lights hid under a bushel. They are not deliberately courting trouble with the union.

It is little known that an immense scraper loader for use on long straight working faces has practically attained success in a western mine. It is less known that a shuttle-loader on wheels is about ready for practical operation. It will journey back and forth along a face delivering coal into a trip at the middle point of its course, thus enabling a few men to get out a big daily tonnage with a remarkably low power consumption. Hardly anybody hears about a new system of mining adapted to a novel type of scraper now getting its finishing touches. Not much is known of several new mine layouts calculated to overcome the obstacles of transportation behind standard loading machines. Yet all these ideas are far beyond the paper-model stage. They are succeeding. And many another idea is obtaining its full measure of success, hidden away in the mines of this country waiting for its time to pop into the light. You'd be surprised!

Despite much stumbling, mechanical loading will be solved for all reasonable conditions. We are well beyond the Kitty Hawk stage of development. Hereafter progress should be rapid. So much cogitating and testing cannot fail of ultimate success.

## What To Do? What To Do?

WHEN it comes right down to it, almost everybody has a direct interest in the welfare of coal. Events in Illinois prove that, these days, when we see the state itself rising in defense of its industry. The butcher, the baker and the candlestick maker in average times can gain great self-satisfaction by rub-a-dubbing in their own little tub about how the "cut-throat" miner and the "baron" operator are scheming to hold up the people. But when an insufferable situation with widespread unemployment, political uneasiness and lack of business in the mines is hung like a stone about the neck of the coal industry, so as to begin to cause distress in the butcher shop, the bakery and the candlestick foundry, then the suffering industry becomes "our industry" and we all rise most indignantly though belatedly to defend it.

In Herrin, down in the heart of the great southern Illinois producing field, there are so many hungry families and unpaid bills that on August 20 a public mass meeting is to be held. The people of Williamson County want to find out exactly what causes this travail and what can be done to relieve it. They propose to have a popular "economic conference"—although they don't call it that—where the best men among miners, operators and business interests will tell their stories. The folks of Herrin are tired of suffering in silence. They want to know just exactly why it is that coal from non-union western Kentucky moves right through their territory bound for market, while their own mines are cold and their men are doing nothing or worse. What they can or will do after they find out, nobody knows. But such a mass meeting never was held before, down there. The very fact of its being called is important.

It is to be hoped, however, that the Herrin men this time keep strictly within the law and refrain, certainly from murder, and even from intimidation. News that they are automobiling into the disorderly territory in Kentucky with automobiles bearing that name of evil connotation "Herrin" would be disturbing were the political control of Kentucky in the hands of men as irresponsible as those in Illinois at the time of the Herrin massacre.

Then, too, here comes the Illinois Commerce Commission. It notes that the Interstate Commerce Commission has raised the freight rates on Illinois coal going into the rich Northwest coal market twenty-eight cents and it formally resolves that this "seriously increases the present depressed condition of the mining industry in Illinois." Then it requests the state attorney general to "take such action, either by injunction or otherwise, as in his judgment may be necessary to adequately protect the interests of the people of Illinois." The new Northwest rates are scheduled for effect September 10 but the sovereign state of Illinois may yet block them, since its commerce commission is taking the field along with nearly a score of lesser organizations.

It is hard to foresee what all this hulabaloo in the interest of coal will do. It certainly ought to help a good many rank and file union miners to realize that with the costs of Illinois coal and of non-union coal where they are, Illinois is pretty sure to go hungry. But the interesting feature of the whole new movement is that an entire state is realizing that the coal industry is not necessarily a thing beyond the gates to be

constantly reviled and spat upon. The state confronts a puzzling situation. The question of the day is: "What to do?"

## Our British Exemplars

GEORGE OTIS SMITH gives us in this issue the high lights of the program of the Liberal party in Great Britain in regard to coal. There are many who believe and still more who fear that we are likely to use the British as our exemplars. We got our union and our pit committee from them. We have followed a long line of their precedents in regard to labor. Let us hope that we shall not get from them that mitigated Bolshevism that the report contains, for in some ways the Sovietism that is unadulterated is better than a Sovietism that is hung around the neck of capital. It is planned in the report that the operators and their employees shall be co-equal directors of industry. The first will be subject to loss of capital and the other subject to nothing, not even worry, for if the enterprise fails they loosen their hold on it and attach their boring tools to another and sink that. The report says that back of every successful co-operative action must be self interest. What interest can there be between those who have all and those who have nothing to lose? But let us take courage. This manifesto on "Coal and Power" has after all only the approval of the Liberal party of Great Britain and we may be able to avoid it despite the readiness with which we take British precedents as our exemplars.

As for its references to the acquirement of coal lands and the leasing to concessionaires, less objection might be taken. Royalties are too high; they might at least be prevented from going higher. Requirements that the concessionaires spend enough to make mines safe, healthful and fit working places do not seem so outrageous. The illustrations we hope to show of the Campine will bear out the advantages of the concession system.

Then there is a further hope. The citizen consumer with his Pecksniffian manner, who has been so disposed to be critical and to wonder why the mine worker was not domiciled in tiled houses with pebble dashed fronts, half-timbered gables and exterior chimneys of the best type, will be given the opportunity to pay in the price of his coal his part toward such a consummation. He will no longer be able to berate. What he demands will be done, and he will pay for it.

We publish E. J. Mehren's reactions on the British situation. He says the British are "complacent." The report Dr. Smith has briefed would suggest that some men in Great Britain are neither complacent nor conservative but have a definite program for dealing with the situation. Alas that it is *such* a program as it is! Nor can we feel moved with admiration and assurance at the British qualities, for a country is as good as its whole people. No one can denationalize the undesirable. The fact is, as Mr. Mehren well says, that only too many in Great Britain are looking to the government and not to frugality and hard work. That statement may not affect all classes, but if it affects a large proportion it is certainly not safe for us to praise the British spirit. Unfortunately, not a few have been disposed to believe in America that our own individualism has of late years lost its sturdy qualities. We, also, desire in a measure a government that will act as lackey to our laziness.

## Strip Mines Full of Pitfalls for the Unwary

Operators Can Easily "Landlock" Shovels Merely by Taking Out All the Coal in the Thoroughcut—Any One of Several Systems Will Prevent Loss of Coal and Useless Yardage

BY GRANT HOLMES  
Danville, Ill.

**H**OW simple a thing is coal stripping—to the uninitiated! The apparent ease with which shallow coal is sometimes uncovered and loaded has baited many a good man into ruin. Therefore, in a time like this, when so many people are going into stripping, including deep-mine operators hard-worn by the gruelling effort to reduce their costs, perhaps it will be helpful to scan the progress of stripping practice and point out some of the pitfalls of the business.

The man making his first venture into stripping ought to be warned against taking all the coal out of his first opening or thoroughcut. A wide bench of coal left in is the one thing that will keep his shovel from getting itself "landlocked" and helpless. He should know how to pile waste banks to protect his boundaries. He should realize the necessity of good tile drainage and of having sufficient pump capacity. He should know the virtues of the several methods of circular and parallel cutting so that he may not lose blocks of his own coal or spend money for unnecessary handling of overburden. Some of these things will be suggested in these pages.

In order to compete with the underground mines, the stripping operator must be able to produce a steady output as cheaply as possible. This fact has placed

stripping on a systematic and commercial basis never before attained. To acquire such conditions, gradual and cautious operations are recommended; the operator cannot expect to make big profits as soon as he commences stripping. The relation between stripping and loading must always be taken into consideration.

### ROBBING THE COAL FACE IS DISASTROUS

Naturally, the fact that without stripping of cover, there can be no coal taken from a strip pit is self evident, but that too much mining will stop the stripping, is not quite as apparent, especially to new operators. The practice of too much mining, more commonly known as "robbing the face," means taking all of the coal out of a cut. When the steam shovel has completed the first or thorough cut, the inexperienced operator proceeds to mine out all coal exposed, at a handsome profit. Each succeeding cut is similarly "robbed." Finally, the steam shovel is stopped by being squeezed between the waste banks and the stripping face, unable to dig any farther.

Each cut has been a virtual thoroughcut, due to "robbing" of the coal. Hence, the shovel has been forced to make immense banks of waste material which occupies at least 25 per cent more space than it filled when in place. Each cut sees the space for waste banks become smaller, without decrease in the cutting until at last the equipment is locked tight, all due to "robbing the face" or neglect of the relation between

NOTE—Headpiece shows a stripping where lack of system has made the entire recovery of the coal difficult if not impossible. Though the surface of the land may be worth nothing, the coal lost by ill-considered stripping reduces appreciably the profit of the undertaking.

stripping and loading. In spite of all advice from old operators and the shovel builders, it seems that many of the beginners must at least try what seems to be most profitable—"robbing the face."

To prevent "landlocking" the shovel, the operator must not expect to make all the money on his coal at once. He should first have a stripping shovel of sufficient size to handle easily the deepest overburden in the field. After making a thoroughcut of maximum width, a strip of coal not over 30 ft. wide may be removed along the edge near the property or crop line leaving from 45 to 60 ft. of coal for a working berm. The shovel then returns making a cut a little less than 30 ft. wide. By maintaining approximately these stripping and mining widths throughout the time of operation, the stripping machine is able to work with ease and speed, placing the waste far enough away to prevent burial of the coal face.

If heavier overburden is reached, the cutting can be narrowed down, as the shovel is operating with the edge of the frame nearest the cutting, in a straight line with the outside edge of the stripping face, thus giving plenty of room for swinging the machine. If a bench or berm of coal is left on which the shovel can stand the success of the enterprise is assured, whereas if this berm is removed, failure is inevitable. The berm should be 45 ft. wide if the coal is strong or 60 ft. if it tends to cave at the edge.

#### IN HAND LOADING LEAVE EIGHT FEET FOR TRACK

Up to 1912 the coal was loaded by hand in all fields, and it is so loaded in some regions especially where bottom is uneven. Fig. 4 shows the most efficient method of hand loading. The stripping shovel operates as near the coal face as possible, enabling the overburden to be dumped far enough away to leave about 8 ft. of space between the face of the coal and the base of the wastebank. The track is laid for the length of the cut in this space. Short spur tracks or sidings are led off the main line to the coal face for loading, thus doing away with track entry cutting which is a heavy expense.

The locomotive engineer places about a dozen empty mine cars on one of these spurs. The coal diggers proceed to load the cars, while on the other spur another dozen of "empties" are being placed. When the first dozen are filled, the miners walk over to the second spur and load the cars there. Meantime, the loads are hauled to the tippie, and more empties placed on the recently vacated siding. This alternate loading on each spur makes a continual flow of coal to the tippie and keeps all hands busy.

As the coal face recedes, the sidings are thrown over

accordingly within shoveling distance. By this time, the shovel has reached the end of the cut; the proper quantity of coal has been mined, making room for the wastebank on the return cut.

In some fields where the coal seam is very irregular, containing many "dips," other methods of loading are adopted. Instead of going to the great expense of maintaining a haulage track on such a bottom, the haulage road is placed on top of the bank near the stripping face. The coal is loaded into boxes or "skips." A locomotive crane operating from "on top" transfers the loaded skips from the pit to flat cars on the haulage track.

On arrival at the tippie, a derrick hoists the boxes up to the receiving hopper. The bottoms of these skips are hinged, enabling the coal to be dumped easily. The biggest disadvantage of this system is the maintenance of two extra machines, the crane and the derrick, besides a locomotive and track. The fact that each skip must be handled six times in one round trip to the tippie, is also against this method.

In 1912 the T. J. Forschner Coal Co. of Linton, Ind., installed a small revolving shovel at its strip mine to load coal. So successful was this machine that now every strip pit where conditions permit, has its coal-loading shovel. These small machines have usually a 26-ft. boom and a specially designed 1½-yd. dipper. Being mounted on traction wheels, no tracks are necessary. An engineer and fireman operate the machine, if it is operated by steam, easily loading 1,000 tons of coal in eight hours.

#### TWO LOCOMOTIVES SHUTTLE CONTINUALLY

Two small locomotives are required to handle the coal without loss of time, for while one is spotting a train of cars for the shovel, the other is hauling loads to the tippie and returning with empties. Either 5- or 15-ton mine cars should be used for steam-shovel loading, those for hand loading holding about three tons.

Fig. 1—Stripping by Team and Scraper

Preferable way of handling the stripping of coal with this primitive form of equipment.

FIG. 2  
Hoisting Boxes to Tippie

Scene at Fuller, Kans. Derrick is hoisting 4-ton skip. Plan of handling coal eliminates some construction and haulage problems but is too slow and expensive wherever conditions do not require its adoption.

The track for either hand or mechanical loading should be built of 40- to 50-lb. rails laid on wooden or steel ties without ballast, as the track must be laid anew for every new cut. In some mines where only run-of-mine is sold, railroad gondolas are run directly into the pit and loaded, standard gage track being necessarily used in such cases.

Years ago much prejudice had to be overcome before the machine loading of coal was accepted as practical. The objection was the excessive breaking of coal, but experience shows that only 18 to 20 per cent of slack, results from steam-shovel loading. One seeming disadvantage is the loading of impurities with the coal, but the installation of picking tables on the tipples has largely solved this difficulty.

The track arrangement in the pit for machine loading is different from a hand-loading layout. Figs. 6 and 7 illustrate two possibilities for mechanical coal loading with their accompanying track systems. The stripping shovel must be moved over from the breast until sufficient space is left for haulageway. This brings the base of the waste bank within five feet of the coal face, accommodation for drainage tiles being necessary. The swath of the coal dug out by the shovel is not over 30 ft. wide, depending upon the depth of the overburden and the capacity of the stripper.

In Fig. 6, a common, but not especially desirable condition of operation is shown. The coal shovel is following the big shovel thus depending upon it for each day's output of coal. If the stripping machine should break down, no coal could be produced until repairs were made. Fig. 7 shows a more advantageous situation in which the coal output is not entirely dependent upon the steady work of the big shovel. If the stripping shovel should break down, coal may be loaded until the end of the cut is reached, and by this plan the continuance of stripping depends upon the loading to provide room for a wastebank. The cuts if long enough will provide a steady output while repairs to the big shovel, however extensive, can be made.

While the coal loading was being developed to its present state of perfection, the stripping part of the business kept pace, the important factors in the operation of the large shovels being ascertained. It was

Fig. 3—Circular Plan of Stripping

With this plan, much track-age must be maintained, but this scheme keeps it to a minimum. An entrance is kept open by piling spoil on each side of the entry cut.

Fig. 4—Economical Way of Hand Loading

Stripping shovel operates as near coal face as possible and dumps overburden so as to leave 8-ft. clearance in front of coal face. Spurs make entry cutting unnecessary.

necessary to learn not only how the shovel should be handled but also where the material should be placed.

Of primary importance in the development of steam shoveling has been the creation of a new type of engineers and cranemen to operate these stripping shovels. They differ from the "old timers" by placing the careful handling of the machine above its yardage. The immense size and great weight of the mechanism has made this necessary, especially as 90-ft. booms and 5- to 8-yd. dippers on shovels weighing 300 tons now are not uncommon.

To keep ahead in the stripping work, two shifts of men are required to accomplish what was formerly done in one shift to the great detriment of the shovel. Consistent, steady running has been found the key to successful operation.

The shovel crew consists of four men. The engineer, who controls the hoisting and lowering of the dipper and the swinging of the machine, is the boss; he receives the highest wages, and his judgment and

FIG. 5

### Three-Hundred Ton Electric Shovel

Eight-yard dippers and 90-ft. booms make the production of strip coal possible even where overburden is tremendously heavy. The length of boom and size of dipper may be increased in order to make deeper stripping possible, but the conveyor in one form or another may step in to meet this necessity, though the variety of the materials handled and of its condition make the use of the conveyor difficult.

Fig. 6—Common but Undesirable Plan

Here the loading shovel depends for each day's loading upon the stripping shovel. If stripper is delayed loading has to stop. Note that coal is loaded on cars running on track on top of coal.

Fig. 7—Loader Can Work If Stripper Is Idle

More advantageous arrangement than in Fig. 6, but big shovel must depend on loader to make room for waste banks. If cut is long enough loader can work even if stripper is off for extensive repairs.

mechanical knowledge should make him worthy of them, for on him depends the welfare of the entire shovel. The other men have a tendency in their work to follow his example, careless or otherwise.

The craneman who crowds or "eases" the dipper in digging and dumps it, is the right-hand aid of the engineer. Upon their team work, depends the work accomplished by the machine, therefore, they should be as agreeable in personality as possible, each performing his duties in perfect conjunction with the other.

If a steam shovel is used the third man is the fireman. He devotes his entire time to stoking the boilers and maintaining the water supply; his skill and intelligence can prevent many shutdowns from leaking flues. He also should be able to make other boiler repairs.

The fourth member is the oiler who keeps open ears and eyes for squeaks, unusual noises, leaky joints, or dry bearings. Too often managers consider this man

an unnecessary expense. This is a great mistake, for his value is inestimable, in view of the repairs and time losses he can prevent. The oilman takes care of the multitude of oil cups and lubricators, and he has also to watch many minor details of operation. In this way he saves the other members of the crew from being distracted from their work.

Four times each day the entire crew of the well-operated shovel joins in a general cleaning, inspection and oiling. The engineer attends to the hoisting and swinging engines, the craneman to all the boom machinery, the fireman cleans the fires if necessary and examines the water pumps, and the oiler sees that the swinging parts and running gears are supplied with lubricant.

Four other attendants to the shovels are known as "sod-hogs." Their duties are to grade and lay track and to clean up the dirt missed by the dipper.

#### FLOODS KEEP STRIPPING FIRMS BUSY

Some fields are so situated as to be entirely free from floods or an abundance of springs. Many stripping properties opened recently are on high ground but there are many in bottom land where drainage is the principal problem. Much strip coal land seems to be diabolically situated near some river capable of overflowing its banks at the slightest provocation. The usual association of streams and strip coal is due to the fact that the river has at some time previous washed the deep soil from the coal, leaving it suitable for strip mining. Hence, drainage becomes an important but often neglected feature of planning stripping plants.

Of course, the operator cannot tell with much certainty what his water problem will be until the work is progressing, but equipment for any emergency should be on hand. Above all other equipment, electric power should be available, and if central station current cannot be had, no better start for a strip mine can be recommended than the erection of its own power plant.

Several small pumping units and perhaps one large unit are necessary. Each unit consists of a motor and direct-connected centrifugal pump mounted on a truck. Discharge pipes made of spirally wound, galvanized

FIG. 8  
Stripping Takes to Hills

Dump house, incline, monitors, approach trestle, tipple and supply track at mine of Beech Flats Coal Co., Rush Run, Ohio. Hilltop stripping has its advantages in the matter of drainage, for the strip pit is not likely to be inundated by the river, but it often complicates haulage to the tipple. Tipples for handling strip coal are as complete as those for deep-coal preparation.

Fig. 9—Rectangular or Two-Pit Method of Stripping

Incidentally this method gives opportunity to protect the edge of the pit against caving, in case it is close to boundary of property. On the thoroughcut, the big shovel deposits waste away from the boundary. Returning to the corner from which it started, it dumps its second cut and about half the waste of the first cut against the boundary. Thus law suits may be avoided.

Fig. 10—Stripping Valley with Two Sets of Equipment

Where the cover is thin in the middle of the property and thick at the sides, the two big shovels first cut down through the middle and then work away from one another. The work constantly retreats toward the tippie as in retreat system of mining, thus steadily shortening haulage with consequent savings. The cutting line is almost straight for both strip shovels.

Fig. 11—If Right-Angle Method Is Unsuitable Try Radial Plan

Where property lines must be preserved, this scheme protects them without leaving a wide strip of coal. Spoil from the thoroughcut along one boundary is piled inside. From the end of this pit the shovel makes alternate short and long cuts, working at an angle of 45 deg. to the property line and dumping back toward it. This fills the stripping face made by the thoroughcut.

iron, connected without the use of unions, are cheap and easily handled.

One of these small units is kept with the coal-loading shovel, which at a short distance behind itself, digs up a small dam between the waste bank and the coal face. The discharge of the pumps is behind this dam, thus keeping the coal pit free from water. If much water comes into the haulage way, a sump is dug at the lowest point, and a large unit installed there permanently, with discharge laid over the wastebank.

#### WET OVERBURDEN AND WASTE WILL SLIDE

Where seepage and springs pour great quantities of water into the cuts, a system of tiling should be laid, if possible. A large main parallel to the cutting is placed in the first cut, below the coal, and openings in this line carry away the water in the first pit. Laterals are attached to this main, laid under the waste-banks as each succeeding cut is made. The openings are located between the foot of the spoil banks and the face of the coal.

Floods are not all the troubles arising from water. The wetness of the overburden is another phase of the drainage problem. If very wet and sloppy, the waste banks will slide down suddenly and unexpectedly, sometimes burying the coal-loading machine or, at least, covering up the coal face. The face of the cutting will also slide down from the undermining effect of springs, perhaps catching the stripping shovel.

Here is where a bed of shale or soapstone above the coal is an advantage, for by leaving in a bench of this material along the stripping face, many slides will be prevented. If that shale or soapstone which must be dug is deposited near the coal face in a small, separate wastebank, and the wet, slippery material dumped behind it, a double-built and double-strength bank results. The burial of the coal face is avoided, as the bank of hard material is a retaining wall for the overburden which would slide down.

Throughout the history of stripping, one of two systems of operation, circular or parallel, has been used with each style of machine, according to its adaptability. The circular system has been proven im-

practical in irregular fields, and wasteful and costly in any field. Therefore, with the building of the modern stripping shovel, parallel cutting came into general use. No one definite method of applying this cutting can be recommended as each field has its own peculiar problems in shape, drainage and depth of overburden. By means of sketches, some of the plans coming to my notice are shown with this article. They will suggest "how to do it" to new operators who may read this.

Figs. 4, 6 and 7 illustrate the methods probably most commonly used and the one applicable to many fields. The thoroughcut is made in the shape of a right angle following the property lines the width and length of the land. The overburden is piled on both sides of this cut. The shovel now uncovers the coal by cuts parallel to the field length, starting with the long part of the initial cut. A haulageway is maintained in the shorter part of the thoroughcut. In hand loading, the coal is mined out of the haulageway, whereas in machine loading it is left in.

#### TAKING OUT BOTH COAL AND FIRECLAY

In some strip mines, the coal bed is immediately above some other valuable material, such as fireclay for brick making. A two-pit arrangement would be desirable in such a case, for loading out both materials.

Fig. 9 illustrates a field opened on a right angle, incorporating the shortest haulageway possible. The sketch also shows another method of handling the thorough cutting to be used when the work is near a property line.

The shovel has started from a corner of a field making the first cut along one side, depositing all waste away from the property boundary. Returning to the corner, the shovel dumps its cutting and about one-half of the thoroughcut wastebank against its boundary. Caving in along this line which might result in heavy lawsuits against the mine owners, is prevented by throwing the overburden in this manner.

Starting from the same corner at right angles to the first cut, the second thoroughcut is made. As the dumping is done mostly at right angles to the digging in the operation of the stripping shovel, a gap has been

left in the spoil banks when the 90-deg. turn is made. This gap will occur the diagonal length of the field, leaving a naturally formed haulageway. If the feasibility of such a haulage gap is not clear, compare the space for wastebank with the spoil to be placed there.

It is not practical to switch one of these immense stripping shovels around a sharp corner. Therefore, four wedge-shaped cuts are next made—two on each side of the haulageway. Thus an easy curve has been produced which the machine can make without backing. Two small shovels are put at work, one loading coal in one pit, the other loading fireclay in the second pit. Track for the coal end of the mine is laid on the coal, but the line for the clay shovel is put down along the base of the adjacent wastebank.

If the material under the coal is not valuable, but a large output of coal is desired, two stripping machines and two coal-loading shovels may be installed by using this 90-deg. field plan, one set operating in each pit. The wedge cuts shown in the sketch would not be necessary in that instance, as neither shovel would have to

Starting from a corner, a thoroughcut is made along one boundary throwing the overburden toward the inside of the property. From the end of this pit, the shovel makes alternate short and long cuts. The object is to keep the machine working at 45 deg. to the property line and dumping toward it, thus filling in the stripping face left in making the thoroughcut.

When a true diagonal position of the field is reached, the second thoroughcut is made along the other property boundary. A repetition of the cutting which took place in the other half of the field occurs until the last cut coincides with the diagonal. The boundaries are safe as the waste has been banked up against them.

If only one boundary was in need of protection, the second thoroughcut would not have been necessary. The operations could have continued from the diagonal by making alternate long and short cuts until the opposite edge was reached.

Many other arrangements or combinations of these systems will suggest themselves as improvements on those described, but some such plan must be used for

FIG. 12

#### Picking Table for Strip Pit

Picking tables of this order are commonly used so that the bogey of dirty coal may be lifted from the name of stripping. Nowadays, some of the most elaborate cleaning and sizing plants are located at the big strip pits. In earlier days coal was sometimes loaded by railroad shovels into gondolas and went to market uncleaned. This gave strip coal a bad name.

make the turn. Each would work up to the corner and then return.

Fig. 10 gives another plan for operating two sets of machines in a field which has light overburden through the center, but heavy at the edges—that is a field in a valley. The thoroughcut is made through the middle for the entire length of the property. At the end of this cut, the shovels diverge. By thin cutting near the haulageway and heavy cutting at the crop or property line, field conditions gradually become such that the two pits are in a straight line.

As with the 90-deg. system, each set of machines works up to the haulage and returns. The operations are constantly nearing the tippie, thus decreasing the length of the haulage, as is the case with the retreating system of underground mining.

#### HOW TO AVOID CAVING AND SPOILAGE SUITS

Let us suppose that two sides of a field are property lines which must be respected, that is, they must be left in such condition that when the stripping is completed that they will not cave in. Fig. 11 gives a method of protecting the boundary without losing a big strip of coal, if for any reason the right angle plan is impracticable in the field being operated.

successful strip mining. Haphazard stripping always results in blocks of coal left here and there in the field, useless handling of overburden and shut-downs. But with a good coal bed, a system and regard for the relations of stripping and mining, the modern stripping shovel will accomplish all that can be desired in overburden from nothing to 40 ft. deep.

The near future will undoubtedly see a machine with a dipper capacity of 12 cu.yd. and of sufficient size to achieve the same results as the shovel just mentioned but with a cover 60 ft. deep.

MUD-SLINGING TANK bespreads mine with rock dust—On the truck of a coal-mine car, W. J. Reid, Superintendent of the Lion Coal Co., at Wattis, Utah, has mounted equipment for spraying the roof, ribs and floor of the mine with a mixture of rock dust and water which adheres to everything it touches like whitewash. With one passage of this machine proceeding at about 1,500 ft. per hour a thick coating of mud is distributed which covers the entire periphery of the heading. This mud dried by the air passing through the mine turns to a fine dust. The rock dust used by Mr. Reid in his demonstration in Mine No. 1 is made from a shale which forms part of the hills in which the mine is driven.

# Concentrating Tables—Their Operation and What Results They Obtain in Cleaning Anthracite

Used First Eight Years Ago — Clean Sizes up to Pea — “Tabled Coal” Demanded in Some Markets—Clinkering Eliminated—Less Ash After Burning—Reduced Labor — Increased Boiler Capacity — Regulatable Ash Content

BY JOHN GRIFFIN\*  
Wilkes-Barre, Pa.

AS HAS BEEN stated previously in this periodical, the art of coal preparation today is in a state of flux, changes and improvements taking place with almost bewildering rapidity. Taking a leaf from the notebook of the metal-mining industry, some anthracite operators years ago experimented with concentrating tables for cleaning the smaller sizes of anthracite. In this case, however, what corresponds to the gangue of the metal mine in its low specific gravity, is the cleaned product of the coal mine, whereas the concentrate of the metal mine is analogous in its high specific gravity to the worthless rock, slate and refuse extracted from the coal.

Concentrating tables have now been in commercial operation on the smaller sizes of anthracite for about four years. Their product, meanwhile, has proven so satisfactory to consumers that in certain markets a definite demand has been created for what is called “tabled coal.”

About eight years ago the first concentrating table was tried on buckwheat No. 4 anthracite. The machine tested was a standard table as used for ore concentration. The trials, however, indicated its practicability and also that better results might be secured by redesigning the machine, giving it a larger deck, better suited to meet the conditions encountered in coal cleaning.

In the spring of 1920, after much experimentation at the testing plant of the Deister Concentrator Co., Fort Wayne, Ind., the first Deister-Overstrom diagonal-deck table designed for coal washing was installed in the Wadesville breaker of the Philadelphia & Reading Coal & Iron Co. This machine was put to work treat-

ing barley, or buckwheat No. 3 coal. About the same time the Hudson Coal Co. installed a duplicate of this table in its Loree breaker for experimental work in cleaning No. 4 buckwheat.

## EXPERIMENTS PROVE UTILITY OF TABLING

The success attained with these admittedly more or less experimental installations led to the adoption of the table at many breakers throughout the anthracite region. It is estimated that over three hundred machines of this kind are now in use and that about 6,000,000 tons of coal are treated by them annually. Not only are these machines employed on the buckwheats Nos. 1, 2, 3 and 4, but tests on pea coal have shown highly interesting results.

Many of the early tables were installed for the purpose of cleaning coal for use in the mine boiler plant. In many cases the use of tables has reduced by half the quantity of ashes and refuse taken from the boiler ashpits and has entirely eliminated clinkering. Furthermore, in addition to enabling the boiler plant to operate at a higher capacity, table-washed fuel has in many cases reduced boiler-room labor between 25 and 35 per cent.

Again, in not a few instances, satisfactory boiler operation has been obtained from table-washed barley, whereas prior to its use a generous admixture of rice or even buckwheat No. 1 was necessary in order to carry the load. The weight of fuel consumed in such cases has not been increased. Results obtained in their own boiler plants convinced the coal companies that the use of tables would permit them to offer the public a superior fuel in the shape of table-washed steam sizes.

FIG. 1  
Cleaning Buck-  
wheat No. 1

The riffles on the platen of this machine appear to be set diagonally. As a matter of fact, the table does not have a rectangular but a parallelogrammatical outline, and the riffles extend in the direction of oscillation. Greater capacity from a given area is thus obtained.

\*Manager, Anthracite Territory, The Dorr Co.

Like the jig, the concentrator table utilizes the difference in specific gravity between coal and slate in obtaining a separation of these substances. The preparation is, of course, wet and takes place on a deck, platen or table inclined both longitudinally and transversely. The transverse inclination, however, is far greater than the longitudinal. This deck is covered with strips or riffles extending throughout its length and is reciprocated approximately 265 times per minute, the amplitude of each stroke being about  $\frac{3}{4}$  in.

The material to be treated, with about twice its weight of water, is fed to the table at its highest corner. Water-distributing boards along the upper edge of the deck keep a sheet of water flowing across it. Under the action of this water and the reciprocation of the table, the various particles stratify in accordance with their respective specific gravities. Thus the heavy uncombined ash-forming substances, such as pyrite, sand, rock, slate and the like, seek the surface of the table between the riffles, by which they are guided to its end where they are discharged. The coal on the other hand, being lighter, is washed across the riffles and into the clean-coal launder or chute.

The above is a general description of the action of any concentrator table. Specifically the Deister-Overstrom coal-washing machine is built with a "diagonal deck." This affords a table, the boundaries of which closely coincide with the well-defined lines of separation between coal and refuse. More efficient washing is thus obtained from a given deck area.

#### DISTINCT SEPARATION FORMS BALD SPOT

The distinct separation between coal and refuse is evidenced by a "bald spot" at the juncture or corner of the coal side and refuse end. Thus all coal is washed

TABLE I—Capacities of Concentrating Table in Relation to Size Treated

Size	Tons of Feed per Hour per Table
Buckwheat No. 1.....	15 to 20
Buckwheat No. 2, or rice.....	12 to 18
Buckwheat No. 3, or barley.....	6 to 14
Buckwheat No. 4.....	4 to 6
Slush.....	2 to 5

off the deck before reaching the end of the table, and the refuse is discharged well away from the coal side. This assures complete separation into a refuse-free coal and a coal-free refuse, without the production of any middlings product requiring retreatment or separate disposal.

Fig. 2—Rice-Coal Tables in the Lehigh Field

In use, a concentrator table is inclined in two directions—a slight longitudinal inclination and a far more pronounced transverse slant. Adjustment of these slopes determines the quality of coal produced.

Fig. 3—Rice and Barley Tables

At present tables are used mostly in treating steam sizes. For this purpose they form part of the regular equipment of many a breaker or washery.

If for any reason it is desired to split the clean coal into two or more products, this may be done with ease. The coal discharged near the feed end of the table will be low in ash, and that leaving the platen nearer the refuse end will be higher in ash-forming material, as this heavy material crosses the riffles more slowly than the lighter coal.

#### SIZE OF MATERIAL TREATED INFLUENCES CAPACITY

The capacity of a coal-washing table varies somewhat, depending upon the size of coal treated, its character (as the difference in specific gravities of the materials to be separated affect the ease of their separation) and also the quality of clean coal desired.

In general, larger sizes of coal can be treated at higher capacities than the smaller sizes. Again, if coal extremely low in ash is desired from a table, the tonnage treated will be somewhat less than that handled under normal operation. The range of capacities given in Table I has been obtained when treating various sizes of anthracite.

The effect of the quality of clean coal obtained upon the capacity of a table is well illustrated by the results obtained on barley coal at a certain breaker near Scranton. When producing one carload of clean coal per day, that is, handling between 50 and 60 tons of feed, the ash in the tabled product was between 10 and 11 per cent. When, however, the output was increased to 85 tons per day, the ash ran 12 to 14 per cent.

Recent tests on buckwheat sizes Nos. 1, 2 and 3 at a breaker in the southern field and extending over three or four days' operation on each size, gave excellent results so far as tonnage handled, recovery of clean coal and quality of product were concerned. These results are given in Table II.

#### EXCELLENT RESULTS OBTAINED WITH FINE COAL

At this breaker, tests were also conducted on pea coal, five carloads being made in two days or in a total working time of 17 hr. This indicated a production of 13.2 tons of clean coal per hour from a feed of 20.2 tons. Analysis of samples of the raw feed showed that it contained 38.5 per cent of refuse, whereas the cleaned product had only 5.74 per cent. Analysis of the refuse discharge showed 2.02 per cent of coal in the reject. These results indicate a recovery of nearly 99 per cent of the coal in the feed, and a removal of 90 per cent of the refuse from the material tabled.

FIG. 4  
Buckwheat No. 4  
Tables

Four tables cleaning this small size of coal between  $\frac{1}{8}$  in. and 65-mesh. In all there are eight tables used in this breaker for cleaning this extremely small coal. Table capacity decreases with a decrease in the size of coal treated. The quality of both coal and refuse may be varied with the setting of the table and the quantity of feed handled.

In the accompanying illustrations, Fig. 1 shows a coal table that cleans No. 1 buckwheat at a breaker in the Lehigh field. Fig. 2 shows four similar tables that clean rice. An 8-hr. test on three of the four tables of Fig. 2 showed a production of 373.7 tons of clean coal, analyzing 13.20 per cent ash. The feed to these tables contained 21.3 per cent ash, and the refuse product leaving them carried 73.9 per cent of ash. Each table averaged 18 tons of feed and 15.6 tons of clean coal per hour.

#### WASHES FINEST SIZES OF COMMERCIAL COAL

Fig. 3 shows two coal-washing tables, one for rice and one for barley, at a breaker in the Lehigh field. Fig. 4 shows four tables out of a total of eight installed in a breaker in the southern anthracite field and operating on buckwheat No. 4. This installation, when six tables are operating, produces 200 tons per day of buckwheat No. 4, analyzing 13 to 14 per cent of ash from a feed containing 25 to 30 per cent of ash.

At a certain breaker in the Wyoming field, a low-ash buckwheat No. 4 is being produced. This is coal that passes through a  $\frac{3}{8}$  in. circular opening, but is retained

reduction in the ash content of the material treated, to handle large tonnages and produce a product of uniform quality from a raw feed of varying quality. When properly installed, they are easy to operate and low in operation costs. Thus, with the table it is possible to effect great reductions in the ash content of the material treated without undue loss of coal to the refuse and with a reasonable capacity. Furthermore, the table is highly flexible in its operation and permits of a fairly definite control in the quality of the coal produced; that is, at the will of the operator, the product may be made either medium or low ash as desired.

### Shall Central Power Stations Leave Cities And Be Re-Erected Near Mines?

The proposal to establish near pit heads a number of superpower stations for electric supply has fired the imagination of laymen and newspaper writers both here and in England, says the *Electrical World*. Even engineers who ought to know better have succumbed to the suggestion. There is no doubt of the savings in the generation of electricity made possible thereby; but the trouble is, and it is an insuperable one, that nature has rarely seen fit to put coal and water together. However, for every ton of coal burned under modern power-house boilers, from 600 to 1,000 tons of water are required to condense the steam discharged from the turbines. That is why superpower stations must in the main be built on large rivers or at tidewater, and that is why the great interior cities of this country and of England are handicapped in the erection of superpower steam stations. Coal is usually obtainable, water is not; and modern stations require a thousand times more water than coal. As a matter of fact, the Waterside station in New York City pumps more water for condensing purposes than the whole city of New York consumes for all purposes, and the same is true of the Commonwealth Edison Co. of Chicago and numerous other public utility companies possessing huge steam generating stations. A station at the coal mine is ideal, but, like many ideals, rarely works out when put in practice.

TABLE II—Tests on No. 1 Buckwheat, Rice and Barley Anthracite

	No. 1 Buckwheat	Rice	Barley
Breaker time, hours and minutes.....	33.27	25.30	23.30
Number of carloads produced.....	8 $\frac{1}{2}$	6 $\frac{1}{2}$	5 $\frac{1}{2}$
Clean coal produced, tons.....	371.55	307.50	243.90
Feed to table, tons per hour.....	19.27	17.95	14.43
Ash Analyses:			
Per cent ash in feed.....	43.30	35.75	33.53
Per cent ash in clean coal.....	15.43	15.03	17.46
Per cent ash in refuse.....	80.60	78.19	74.72

on a 200-mesh screen. After passing over the tables in this plant, the ash in the finished product ranges from 9 to 11 per cent. Because of the extremely small size of the material treated and the low ash in the product, the feed averages only about two tons per hour per table. The result of one month's operation showed that the feed to the tables averaged about 29 per cent of ash, while the average ash in the clean coal for the same period was 9.5 per cent.

Tables employed to clean the steam sizes of anthracite have demonstrated their ability to effect a great

# A British Solution of Coal-Mining Problems

Would Have Nation Acquire Ownership of Coal Lands and Leave Operation in Hands of Concessionaries Subject to Leasing Agreements, Providing for Better Housing and for Royalties Based on Coal Values

BY GEORGE OTIS SMITH  
Director, U. S. Geological Survey,  
Washington, D. C.

"COAL AND POWER" is the title of a concise and readable report issued July 12 by a committee of the Liberal party under the leadership of D. Lloyd George. The linking of the reorganization of British coal mining with the larger program of the rejuvenation of British industry is doubly significant in a semi-official document appearing at the close of the World Power Conference in London. Mr. Lloyd George's committee concludes its proposals with an eloquent reference to the first industrial revolution that began one hundred and fifty years ago, when steam brought in its train evils as well as benefits—"a dirty and smoky civilization."

Now, we are entering the early stages of a second industrial revolution when electricity may be the means of repairing these evils, by giving us a clean civilization and by decentralizing industry thus rendering possible a healthier distribution of people over the face of the country. The Lloyd George report has met with criticism as a political paper, but the Liberal party has clearly sensed the great possibilities of a better utilization of Britain's coal resources, and has stated plainly the social ends to be attained—that much is above party and indeed may be common property of all nations.

The dissatisfaction with existing conditions which our British cousins feel is all set forth as the premise of this report, and it all has a familiar sound. The miners complain of inadequate and unequal wages, of housing conditions worse than those of other workers, of excessive royalties to land owners (a burden to the industry actually small but psychologically of considerable weight with the miners) and of non-participation in the control of the industry in which they invest labor and life.

The mine-owner is likewise dissatisfied; labor unrest and political action interfere with economic law; exactions of landowners make efficient operation still more difficult; and absenteeism and shortness of working hours prevent greater production. The consumer in turn objects to the price of coal, which has risen more than 100 per cent, whereas cost of living has increased 69 per cent, and miners' wages, only 66 per cent. The British consumer suspects the coal merchants are making too much, and he freely charges that either bad organization or profiteering is the explanation of the price he pays.

More emphasis, however, is laid on the failure of

the coal-mining industry adequately to serve the nation; high costs of coal production threaten to curtail Great Britain's foreign trade, which is vital to national prosperity; coal is wasted at the mines and uneconomically used in both factory furnace and domestic hearth; and here the first allusion is made to electricity and a larger supply of cheap power to industry, with a large annual saving of coal consumed.

Only one high light appears in the dark picture thus portrayed by this committee: the industry has worked out in its agreement of 1921, modified in 1924, a practical basis for the division of proceeds between capital and labor, here termed "a very remarkable achievement."

Before presenting the essential principles underlying the reform of the coal industry, the committee clears away the underbrush that obstructs vision, by rejecting all proposals for nationalizing or socializing

THIS report would have the working man a part of the governing body in the operation of coal mines. It recognizes the Pit Committee as a valuable restraining influence on the conduct of mines. It declares State control of industry was successful only because "an unlimited market for war products and no limit to the price which would be paid" facilitated administration. It views many older operations as uneconomic and would like to see them wiped out by a vigorous competition.

the mines. Those who point with pride to the success of State control of industry during the war are reminded of the reason why: "an unlimited market for war products and no limit to the price which would be paid."

The elimination of private capital by whatever name it may be called is believed to promise no real advantage to anybody; instead, constructive reforms are sought, "without depriving the industry of the essential vitamins of private enterprise," for "experience is overwhelmingly against the successful administration of a business enterprise by a bureaucracy." Italy is now in fact denationalizing, while in Germany "at this moment the State mines are being made over to private companies."

The constructive program of reform set forth in this report starts out with the proposal for the State to acquire control of the coal resources by purchase of property rights from the 4,000 royalty-owners. The purpose of thus vesting in a single central authority the control of the coal measures arises from the conception that in a modern industrial society the State should not undertake creative and productive functions but rather "should see to it that the necessary conditions shall exist in which the creative enterprise and energy of its citizens can most effectively operate."

With 4,000 royalty-owners, there plainly can be no far-sighted or co-ordinated administration of the national mineral estate. In granting leases to State-owned coal, the Royalty Commissioners can select lessees best capable of working the resources efficiently,

which in the majority of cases would be the present mining companies, but also leases might be granted to co-operative societies or miners' guilds, the sole test being capacity to undertake the business.

Amalgamation of companies or of mines up to the limit of efficient units of operation and management should be facilitated, but in the main the initiation of schemes for such grouping "should come from inside the industry," amalgamation being thus "piece-meal, scientific, and in the main voluntary instead of wholesale and automatic." This policy of removing obstacles to larger and better mines is worthy of adoption on this side of the Atlantic.

Next in order is the proposal to alter the status of the miner, from whom the industry is getting neither the best nor all he can give. The British mine worker has a heritage of accumulated knowledge and experience, but his thoughts operate in a single channel, namely, wage negotiations, where moreover there is antagonism rather than co-operation with capital and management.

Except for collective bargaining upon wages, these million British miners, who are citizens of the Empire, have no say in the affairs of the industry in which they spend their lives, although they are just as much affected by the prosperity of the industry as the shareholders. The miner, therefore, cannot be expected to forego any longer an effective voice in policy but the road of advance here pointed out is not to discard the experience of initiative and management on the part of the mine operator but to bring about co-operation between mine-workers and mine-owners on "terms which share knowledge and responsibility for the general policy between the two, but do not impair efficiency in the execution of an agreed policy."

A mine, like a ship, must be under the direction of an executive with authority, "whose duty it is to make decisions and to give orders which must be obeyed." Experience has shown however that a pit committee "both helps the management to come to a right decision and prevents them from coming to a wrong decision." Such pit committees, as well as the district mining councils, should consist of equal representation of management and workers, and their functions would include "the safety, health, and welfare of the workers, and the maintenance and increase of output."

"The interests of capital and labor in these matters are fundamentally the same." Except as these common interests are yoked together, there will continue the antagonism which expends energy which ought to be directed to one common end. Only by accepting the responsible co-operation of the miner can the operator expect to educate him regarding those economic laws which express the necessity of making the industry pay.

An interesting side light is thrown on the British problem by the statement that war and coal control "retarded the natural process of obsolescence," with the result that both labor and capital are engaged in mines

where neither can earn its wage. "Coal ceases to be an economic asset when it is only obtainable under grossly uneconomic and uncommercial conditions"—a stage believed to have been reached in some of the older pits in Great Britain. So it seems, the survival of the fittest is an economic law that must be allowed to operate on both sides of the Atlantic. Therefore, the Committee attaches great importance to the progressive substitution of new mines for the older ones. It is the key to the problems of better housing and of wage disparities. To pool all mines would involve grading down, to open better mines means grading up.

Housing conditions, of course, vary greatly in the vicinity of British mines as they do here in the United States, but the general squalor and lack of sanitation as described in this report are far worse than the worst even in the older camps in our coal regions. Therefore, the committee makes it a cardinal part of its proposal that the Royalty Commission will insist as a condition

of a lease that a generous and enlightened housing scheme is undertaken. It is this power of attaching conditions that gives the State the power to wisely regulate the industry, but that regulation must be based on clearly understood general principles.

Royalties should be exacted not with any aim of making a profit to the State, as the primary need is coal at the lowest possible price for the use of industry in general. The royalties on new leases should be graded

so as to minimize the difference between rich and poor mines, even exempting mines with poor seams.

A National Mining Council is proposed as a part of the machinery for securing full co-operation in the industry, by including more general representation on both sides; such a body could advise the Royalty Commissioners in matters of policy, administer the National Welfare Fund, and keep the public informed on the facts and so allay suspicion. In only one point is it proposed that the National Council have any part in fixing wage rates. In the case of a deadlock, the issue is to be referred to this bipartisan Council and no strike or lockout can take place until its report has been published.

The legislative recommendations submitted perhaps have less interest to the American reader of this report, but throughout the logic of the British situation there described and of the remedies there proposed is a logic that appeals to those of us who seek peace and prosperity for the coal mining industry in the United States. The hundred and thirty-odd small pages sparkle with phrases that help to hold the reader's interest, such as: "the essential vitamins of private enterprise" or "bad housing means a tragic waste of human material."

Indeed, a half dozen sentences can be quoted that brilliantly summarize the fundamental premises of this report: "We are once more drifting into a head-on collision between those who believe nationalization solves everything and those who believe the only course is to leave things alone. It is highly undesirable that a

---

**T**HE Liberal Party of Great Britain under the leadership of David Lloyd George has brought out a semiofficial program condemning national operation of coal mines but advocating a leasing system closely comparable, it would seem, to the methods of European continental countries where the ownership of minerals is vested in the state and operators are concession holders subject to State regulations which dictate economic policies as well as safe and hygienic operation.

---

great industry should be made the plaything of party conflicts. There is an immense difference between running an administrative service and producing commodities or raw materials for sale in a competitive market.

"No conceivable reorganization of the industry can evade economic laws and escape the necessity of making the industry pay—unless indeed it is proposed to treat the mining industry in the same way as the Navy or the Army, a point on which the taxpayer would have something to say. Everything, wages, profits and prices, depends directly upon the efficiency both of miner and management; unfortunately—mere love of work for its own sake is not an all-sufficing incentive.

## England Five Years After the Peace Still Is "Seeing It Through"

By E. J. MEHREN  
Vice-President, McGraw-Hill Co.

THE WAR is past history in America, but current history in Great Britain. So, indeed, it seems after spending a week in Britain's capital, conversing with her men of affairs and listening to addresses by her business leaders and statesmen. True, there are war scars in the United States, scars that will never be erased. We are mindful of the men who died in the great struggle; we have great numbers of disabled veterans. On the financial side we still have, and will have for many years, a war-swollen budget and correspondingly increased income taxes. But, by and large the war shadow has thinned out. In the last two years we have had "good times." Our war-time income tax rates have been twice reduced. Certainly the way is not blocked by serious obstacles. The difficulties we foresee are merely the fluctuations which, except for the "panic years," one might say are normal to business.

Not so with Britain. The war is only a yesterday with her, and the consequences are still sharp upon her. I do not mean that she is discouraged; that word has no place in the British vocabulary, nor has the state of mind it indicates any place in British consciousness. But the burdens that weigh her, the obstacles still to be overcome, are fully appreciated and are a stock subject of discussion with all her thinking men.

To enumerate some of the troubling factors: 1. There is still large unemployment—though the amount is lessening. 2. There is marked depression in the "engineering trades," as they are called here—ship-building, machine-tool building, and the metal fabricating industries generally. In construction there are few large projects in hand, though there are a few that, after long delay, now seem likely to be taken in hand. 3. A new housing bill, that will again dip heavily into the national and into local government treasuries—and increase, accordingly, national and local tax burdens—is before Parliament. 4. The income-tax rate on even small incomes is 4 shillings 6 pence per pound sterling, or 22½ per cent. The super-taxes are very heavy. 5. The Continental problem is acute and the consequent uncertainty, the upset exchanges, the diminished purchasing power, curtail British export markets. 6. Finally, the never-ending exchange of views, with their Continental war Allies, on German reparations, keeps before the British people constantly the fact that peace, though declared five years ago, is not yet here. There

The mainspring of efficiency must be the actual personal responsibility of the mine-owning concern for producing coal at a remunerative cost. It is mainly by enabling the miner to increase his output that better wages for himself, more prosperity for the industry generally and cheaper coal can be secured."

Nearly a half of this short report is devoted to the title, Power, and is an appeal for the better use of coal by its economical conversion into electrical energy. But interesting as is this strong statement and gratifying as are the frank references to the better status of the American industrial worker, it is another story, though an appropriate sequel to the British report here reviewed.

is cessation of military activity; there is not that accord which is peace in actuality.

In private conversation one gets an even more serious picture of England's difficulties, for there the talk turns to social conditions. Briefly, the burden of these conversations can be reduced to just this: that the altruistic promises of war times and the coddling of politicians have taken from the mass of British workers a sense of responsibility for their own welfare and led them to expect the government to take care of them.

Such an attitude, of course, leads, and has led, to shiftlessness, inefficiency when at work, failure to provide for the rainy day—in a word, all of the economic vices of a dependent, spineless people.

The worst of the difficulty is that no one with whom I have spoken about this attitude of the people seems to have any hope for early improvement. The politician—not the statesman—is the ruler of the day, and as with us, he does not hesitate to sell the public treasury in order to advance his personal interests.

Withal, though, it should be repeated, that the Englishman is not discouraged. He has lived through a lot. He hopes that he will live through this trying period, and that a better day will come.

His way is not our way. We would think that his more or less complacent attitude might be fatal. He believes that the situation will turn out all right; we would fear that it would turn out all wrong unless vigorously handled. (One recalls our Unemployment Conference of some years ago.) We, I hope, would turn, so long as possible, to private measures of relief. The British have turned to the Government. The difficulties, of course, were very great; the amount of unemployment, for example, quite large. Possibly with similar conditions we would have been forced to a similar solution, but I am inclined to believe that the British tap the national treasury with less hesitation than we. The actual war, let us recall in possible explanation, lasted twice as long for them as for us.

But though our methods might differ from those of the British we cannot withhold our admiration of their sterling qualities. Similar conditions would put us in a panicky condition. They go on hanging out their sign "business as usual," confident that eventually all will be well.

Looking back on their long and brilliant history, we, too, can feel confident that somehow the Briton will come out on top. Trial and difficulty develop stamina and character. They are developing them right now in business circles. In the wage earning classes the tendency is in the opposite direction. Eventually, under the example of conscientious leaders, even that tide should change.

# In Any Coal Mine Electricity Will Bear Watching\*

Use of Electric Current Underground Is Safe Only if Properly Guarded—Shock, Gas Ignition, the Explosives Hazard and Mine Fires are Some of the Dangers to be Forestalled

BY L. C. ILSLEY  
Engineer, U. S. Bureau of Mines  
Pittsburgh, Pa.

IN ALL coal-mine applications electricity cannot be considered as other than a hostile friend. Its service to the industry is inestimable, its utility unquestioned, yet just so long as this invisible power is not adequately and scrupulously safeguarded, its hostility is liable to be felt. Although the adoption of this form of energy has done much to reduce the hazards of shotfiring and mine illumination, it must be carefully handled even in these uses. In fact, it will bear watching everywhere. And in order to reduce its hostility, mine operators should give serious thought to the prevention of shock, to the avoidance of dust and gas ignitions, and to the elimination of the explosives hazard, as well as to the prevention of haulage accidents and mine fires.

In making provision against electrical shock, the primary consideration is the voltage of the circuit. No one can be sure that he will be immune to even a 110-volt circuit, provided he makes such complete contact with it that the full current passes through his body. As the potential of the conductor increases so does the danger incident to contact with it.

Because of a lack of room, insufficient light, the presence of moisture and for other reasons, the underground worker is less readily guarded than the man employed upon the surface. All stationary motors underground, as well as switchboard frames and metallic casings containing electrical parts should be permanently and effectively grounded.

Substations and other places where it is dangerous for men to congregate or loiter, should be fenced off and only such persons as are required to perform the

\*Abstracted from a paper by Mr. Ilsley, presented before a recent safety meeting of the National Safety Council, St. Louis, Mo.

Fig. 1—Testing Gallery of the Bureau of Mines

In this or a similar chamber all manner of electrical devices for use in mines are subjected to various electrical tests to determine their fitness to bear the permissible label. Observations may be made through the shielded windows.

Fig. 2—An Unguarded Trolley Wire

This trolley wire extends across a room neck where loose rails have been stored along the rib. A man entering this room is liable to strike his head against the trolley wire or to touch it with a drill or auger held upon the shoulder. A serious accident may result.

routine work of the mine should be permitted to enter the inclosure. Maximum feasible clearance should be allowed all conductors and in so far as practicable they should be confined to one side of an entry or other passage.

## EXPOSED CONDUCTORS SHOULD BE GUARDED

Where of necessity men must work regularly under trolley wires or other conductors, these should be guarded. When men are actually working upon an electric circuit, precautions always should be taken to render it impossible that such circuits should be unexpectedly energized by the closing of a switch or by some other means.

A recent step toward safety in coal production is the wireless mine. Though the chief purpose of keeping all conductors out of the underground workings is to obviate the explosion hazard, this provision greatly reduces the danger from electrical shocks. Two large operators already have begun the use of storage-battery locomotives for all classes of work underground, thus doing away with all permanent wiring inside the mine.

Second to the danger from electric shock is that from gas ignition. Three conditions are necessary to render possible an ignition of gas from an electrical source within a mine. These are: (1) An accumulation of methane or other inflammable gas; (2) a flash or arc from an electric circuit or machine; and (3) the flash or arc must take place at the point where the accumulation of gas has occurred.

Fig. 3—Trolley-Wire Protection Is Good Insurance

Where trolley wires or other conductors cross room necks they should always be inclosed by guard boards held by strong iron braces affixed to the trolley hangers. An occasional bump on an unwary head is much better than a death-dealing shock.

For methane the proportion of intermingled gas necessary to form an explosive mixture lies between 5 and 15 per cent. The spark or flash liable to cause an explosion may be extremely minute. For instance, the tiny spark that may be evolved from a small hand-operated blasting machine is sufficient to set off the gas; or the heat of a 2-volt, 1-amp. electric bulb is likewise ample.

Accident prevention, therefore, signifies keeping such tiny sparks away from the places where gas may possibly accumulate. Pieces of electrical apparatus approved by the Bureau of Mines for use in gaseous atmospheres are safeguarded in various ways. Thus, electric lamps are provided with a bulb-ejecting device that kicks the bulb out of contact in case the glass is ruptured, thus cooling down the glowing filament and preventing it from igniting any gas surrounding it.

In like manner the spark-producing parts of approved electric motors or other machines are so inclosed that any sparks or flashes evolved within the equipment during operation can only ignite the mixtures contained within the compartment walls.

In many mines much apparatus, from a safety viewpoint, may be considered substandard. Such equipment, while built along explosion-proof lines, would in many cases allow flame to pass through the joints. The advantages inherent to permissible equipment are as follows: The apparatus is constructed in accordance with drawings on file with the U. S. Bureau of Mines and the design cannot be modified without due consideration to the effect the changes might have upon safety. Special attention is given them while in process of manufacture. Most companies have special factory inspection sheets that must be filled out for each approved machine calling attention to numerous parts that need specific treatment.

Permissible machines are subjected to actual tests to prove their mechanical strength. They are tested in gas to establish their ability to retain all flame within their inclosures, inspected to insure that they have no through openings leading to their interiors and to see that all bolts are securely fastened. Permissible com-

partments are given special attention at the points where wires enter them. These places are frequently overlooked in unapproved equipment.

In the recent past more attention has been given to the prevention of coal-dust explosions than to any other class of mine hazard. The conditions that favor such explosions from electrical ignition are a dense dust cloud in the presence of an electric arc or flash.

Dust may be raised in a cloud within the mine workings in any one of several ways. For example, a fall of coal or rock may stir up any dust on the sides or bottom of a roadway. A runaway trip may knock down timbers and release the dust resting upon them, or a blown out shot may raise dust in a room. A coal-cutting or loading machine operating in dry coal beds may, in the regular course of daily operation, create clouds of dust.

Electric flashes may occur from a broken lamp bulb, from the blowing out of a fuse, by the operation of a circuit breaker, by the throwing of a switch, the flash of a commutator, from the arc of a trolley wheel or from a broken trolley wire, light wire or feeder, from a short circuit of lighting or feeder cable, or in one of many other ways.

Direct ignition does not constitute the greatest danger of a dust explosion but rather indirect ignition. That is, while it may be difficult to secure exactly the right combination for an electric ignition of coal dust, it is comparatively easy to ignite a small pocket of gas. Such an ignition in turn may stir up sufficient dust to propagate the explosion throughout the mine and prove a hundred times more disastrous than the gas explosion alone would have been.

In seeking a preventive for dust explosions, therefore, one must not only eliminate direct ignitions of dust by electric arcs, but also prevent ignitions of gas. In case gas ignitions occur, the dust throughout the mine either should be so thoroughly saturated with moisture or intermingled with inert non-combustible material as to be incapable of propagating an explosion.

In present-day mining, electricity and the safe han-

Fig. 4—A Permissible Electric Cap Lamp

For actual work at the face the electric cap lamp has largely supplanted the old flame safety lamp. For this purpose, it is lighter, more efficient and gives a steadier and more powerful illumination.

ding of explosives are closely associated. Electrical shotfiring is highly popular. A number of electrical problems are involved in bringing the current to the detonator when and in the quantity needed, as well as in keeping it away from the detonator at all other times.

#### TRANSPORT EXPLOSIVES IN INSULATED BOXES

To fire an electric detonator may require only 0.35 to 0.50 amp. of current. As a consequence, all stray currents must be carefully kept away from the ends of the detonator wires. Nor can anyone be careless with these wires when near an electric circuit, no matter how low its voltage or how seemingly insignificant the current carried. Detonators accordingly should be carried to and from the mine in insulated boxes, and when preparing for a shot care should be taken to see that the ends of the wires do not come

lines extend outside the mine they should be protected from lightning discharges. Ample switches should be provided for keeping the circuit open except when shots are being fired. Rubber-covered wire should be used for temporary and portable firing lines in order to minimize the danger of shots being fired prematurely should these conductors come in contact with other circuits.

Attention of the Bureau has been called to the overheating of detonator leg wires and the ignition of gas from this cause. A preliminary investigation of this hazard has resulted in the following recommendations: (1) Detonators should be connected in parallel-series, series-parallel, or straight series. (2) The current should not be allowed to flow through the connections more than 0.2 sec. (3) Electric detonators with copper lead wires should be used. (4) The standard volt-

FIG. 5

#### A Safe Substation

All danger points in substations should be effectively fenced in. The word "Danger," which is well understood nowadays by every one in America no matter what may have been his native tongue, should be prominently posted at conspicuous points.

in contact with live electric circuits or other electrical apparatus.

Black blasting powder is readily ignited by electric flashes; consequently great care should be exercised to keep the containers of such powder away from all electric wires and apparatus. All powder should be transported in special cars or boxes, so constructed that no metal on the inside of the compartment, such as nails, screws or bolts, may carry electric current from the outside to the explosive.

Not all blasting machines are safe for use in gaseous mines. Even the little hand-operated device commonly used for firing from one to three shots is capable of producing a spark that may ignite gas. Machines on the permissible list of the Bureau have been cured of this danger and while satisfactory for single-shot work, they do not emit a spark capable of igniting methane.

Permanent lines used in electric shotfiring should be kept away from other electric circuits. Where such

age of the firing current should be the lowest that will satisfactorily fire all of the detonators as connected. Thus, if a 220-volt circuit is ample to furnish at least 2 amp. of current to every detonator, a 600-volt circuit should never be used. (5) The firing circuit should not be grounded.

In any shotfiring system, the circuit should be so arranged that not less than 1.5 amp. will pass through the bridge wire of each detonator. Though a small current may fire some detonators, they vary appreciably in the resistance they offer, and sufficient current should be provided to assure the detonation of all of them.

Haulage accidents rank second only to falls of roof and coal in the toll of life and limb which they exact. Statistics show that 341 fatalities occurred underground in the year 1921 and 340 in 1922 from mine cars and locomotives; 25 and 32 fatalities occurred on the surface from the same causes during these respective periods. Though the record of these accidents is

not segregated as to the type of haulage, beyond question a large proportion of them occurred in connection with electrically propelled locomotives.

#### THIRTEEN PERTINENT SAFETY SUGGESTIONS

The following suggestions may be offered as partial remedies for electric haulage accidents. (1) Provide good brakes on all haulage equipment. (2) Provide a good roadbed, track of ample weight and suitable frogs and switches. (3) Provide a separate manway; keep the haulageway clean. (4) Where men must travel on haulageways, provide sufficient plainly marked man-holes or refuge holes and proper means of access to them. (5) Keep roadways well lighted. (6) Provide ample clearance on at least one side of the roadway. (7) Keep the timbering in good condition. (8) Provide a tail-light on all trips. (9) Provide ample head-lights. (10) Provide derailers or runaway switches on

bulbs may start a fire from the heat generated by them if they are installed too close to flammable material.

Many of the foregoing dangers may be obviated by the proper installation of apparatus and circuits. Electrical machinery should be installed in spacious, fire-proof rooms and be well supported on substantial frames set on fireproof foundations. Insulators should be placed sufficiently close together to keep the wires from touching coal, rock or timbers. Wires should never be strung over timbers or in places where they cannot be readily inspected. Temporary wiring should be discouraged. Stations containing oil-filled equipment, such as transformers, should be so arranged that if oil is spilled it will not escape from the room.

All circuits and apparatus should be of sufficient size to perform their functions without overheating and should be protected by current-interrupting devices against sustained overloads. Automatic reclosing cir-

#### How a Dust Explosion Looks at the Mine Mouth

This particular explosion was staged purposely in the Bureau of Mines experimental operation near Pittsburgh, in order that its effects might be closely studied. Much of our present-day knowledge of how to make coal mines safe has been derived from just such experiments as this.

all slopes and planes and gongs on all locomotives. (11) Prohibit excessive speeds. (12) Enforce discipline, especially in regard to riding on locomotives or trips. (13) Prohibit the making of flying switches and eliminate the pushing of trips.

Next to open lights, electricity presents one of the most prolific sources of mine fires. Any machine that is overloaded or that has become worn out in service may break down, causing electric arcs and flashes capable of igniting any inflammable material that may be at hand. In fact every electric circuit is a possible source of fire. Circuits may cause flashes when the wiring becomes grounded, when the circuit is opened under load (accidental breakage of the wires by a fall) and by the short circuiting of conductors of opposite polarity. Certain electrical devices, such as switches and circuit breakers, flash and give off arcs during normal operation. Oil-filled apparatus is especially dangerous if the oil becomes ignited, due to the failure of the equipment. Stationary electric lamp

cuit breakers are proving successful on main-line circuits, but would probably add to the fire hazard if installed on branch lines.

Rooms containing electrical equipment should be kept free from inflammable substances. All wiring should be kept clear of all such materials, and firefighting equipment should be kept in every underground station. This should be of such a nature as to be effective in coping with electrical fires. Grease and oil should not be allowed to collect on or about electrical apparatus.

In certain cases electricity has increased the fire hazard in mines, but when it is used for mine illumination or for shotfiring the opposite is true. The electric cap lamp has replaced thousands of open lights which have always been a potential fire hazard. Electric shotfiring does away with the fuse or squib and in many cases with the open light for igniting it. It thus appreciably reduces the fire risk. One chief mine inspector affirmed that the electric cap lamp alone is worth the cost of the Bureau's electrical section.

# Rocky Mountain Men Strike New Note in Dusting

All Adobe Not Equally Good—Danger of Siliceous Dust Questioned—Best Dust Wasted in Surface Grinding—"Mudizing" Idea Stirs Up Debate—"Days of '49" Turns Rock Springs, Wyo., Into Rip-Roaring Town

COAL MINING men from all over the mountainous West spent three days in Rock Springs, Wyo., last week delving into the problems of rock dusting and coal loading. They also banquetted royally with the folks of Rock Springs, took many a whirl at the old-fashioned faro and roulette, visited the mines of the region and watched a Wyoming state first-aid meet on the last of their three days—Saturday, Aug. 9. It was the summer session of the Rocky Mountain Coal Mining Institute.

The technical sessions brought out data about the rock-dusting methods now prevalent in New Mexico, Utah and Wyoming and which are getting started in Colorado and the results of some loader experience, principally that of the Union Pacific Coal Co. at its Reliance and Hanna mines. These sessions also gave opportunity for some discussion of mine fires and methods of controlling "bumps" in coal seams, not to mention some frank talk about what ails the coal industry. President Eugene McAuliffe of the Union

Pacific Coal Co. was a main contributor to this. President William Littlejohn of the Institute and Vice-President Brunell presided, aided and abetted by Secretary-Treasurer Benedict Shubart.

The hospitality of the dusty city of Rock Springs—a community of 9,000—made a deep impression upon the visiting Instituters, many of whom had never been in Wyoming before. They had pictured the town as the dirty western coal camp it was during the early years since coal began to be produced there in 1867. They found some handsome buildings, including the new Elks home where the meeting centered, some stores, a theater, a lighting system and a hotel or two that would do credit to a much larger city, and about everything else considered necessary in small city life except one municipal ingredient—green grass. The blades of grass in Rock Springs can be counted on the fingers of an armless man—almost.

The faro and roulette of Rock Springs were not an integral part of the city. They were resurrected from the distant days when Rock Springs, was a roaring gambling center along with Butte, Mont., Carson City, Nev., and the other famous hells. "Them days is gone forever," but a few Rock Springs gentry got out their four-gallon hats, slipped unaccustomed feet into high-heeled boots with scroll work on the legs, slung big sixes on their hips, and opened up a lot of games in the "Days of '49" entertainment on the second night

of the meeting. The institute never fails to "register."

The banquet on the first night, at which George B. Pryde, vice-president of the Union Pacific Coal Co. presided, was another handsome bit of entertainment by the city. About 400 were present. Mr. Littlejohn, whose brogue is a standing target for fun at all Institute meetings—Ben Shubart contends Littlejohn speaks with a thistle in one hand and a shamrock in the other

—was one of the speakers. S. W. Farnham, chief engineer of the Goodman Manufacturing Co. was another and T. T. Read of the Bureau of Mines added a gracefully humorous wind-up. Then an excellent local orchestra and the girl scouts of the town entertained, the girls staging a take-off on the day's technical session of the Institute, even to the cigaret which K. H. Marshall of the Bureau had carried to the speakers' table.

The summer meeting wound up Saturday with a demonstration by the Bureau of Mines of dust explosions following the state first-aid meet, in

Rock Springs' First-Aid Park. The only business transacted by the Institute was the unanimous adoption of a long report by its safety committee and a decision to encourage the states of Wyoming, New Mexico and Utah to follow the lead of Colorado in recognizing the miners' competency certificates issued by that state.

The adobe dusting system used by the Phelps Dodge Corporation at its mines in Dawson, N. M., was described by William Moorehead. He told how the dust is gathered outside the mine by a clamshell bucket and hauled in railroad cars to the mine where it is loaded into mine cars. It is scattered on the main haulways by hand after all loose coal has been removed from the mine at least down to a point three inches below the rails. This dries out and is spread both by passing trips and by trees which are dragged through the mines at intervals, usually during the night.

Also adobe dust is sun dried and screened outside the mine and the finest of it, passing a 20-mesh screen, is blown into the intake air course at intervals through holes in the stoppings. Further direct application to roof and ribs is made by using the Cement Gun. The wet method of deposit is far more satisfactory than any other, Mr. Moorehead said, because it reaches every crevice and causes the rock dust to give a strongly adherent coat to the roof and the sides of the entry. Also it can be deposited in a thicker coating than dry

## "MUDIZING," A NEW SAFETY TRICK

ONE of the most talked of subjects at the Institute meeting was the sort of safety "dusting" now practiced by the Lion Fuel Co. at Wattis, Utah. Superintendent W. J. Reid saves the cost of grinding rock dust by substituting adobe dust mixed thinly with water. This is sprayed through the mine by a blower and tanks, making a coating about 1-32 in. thick. He insists it is as effective as dry dust and is so cheap a process that he can afford to cover the mine frequently enough to keep down the percentage of accumulated coal dust. He has been "mudizing" about two months and says the coating dries in 48 hours, leaving thereafter a constant dusty surface which he thinks would be effective in stopping the spread of explosions. He has doubters.

fine dust. The mud coating protects the coal from slacking.

The Phelps Dodge Corporation also waters its mines thoroughly, carrying water lines to within 20 ft. of every face, but main dependence is placed upon the dust. This is not only applied wet and dry as described, but also is provided in the form of rock-dust barriers. Roof is brushed up high enough to erect 16-trough batteries and still leave 6 ft. of headroom. In order to prevent sagging of the troughs in the middle they are erected, on wide entries, in double rows. Mr. Moorehead said his company does not have any fixed maximum lengths for such troughs but they are always short enough to avoid bending under the weight of the rock dust—which is composed of concentrator tailings from a near-by mill containing 97 per cent incombustible matter. About 50 cu.ft. of this dust is loaded on each barrier of sixteen troughs.

Mr. Moorehead said the adobe dust spread on the roadways costs 10c. per running foot, and when stirred up according to the Phelps Dodge plan, is good for one year. Therefore 6,000 ft. of entry could be spread with dust for \$600 a year. One man is assigned to every 6,000 ft. to clean up the roadway and rake over the dust. This costs \$1,900 a year, figuring on 250 days' work at \$7.60 per day. Thus the cost of upkeep per running foot of entry is 31.7c. per year, and this plus the 10c. per foot for application makes the total cost on roadways 41.7c. per year. "Mudizing" entries on the other hand

costs the operator only 0.013c. per running foot. Ninety-nine per cent of the coal operators do not know definitely how explosive their mine dust is, according to K. L. Marshall of the Bureau of Mines, who made a short but pointed talk on coal dust, using samples to illustrate what he had to say. Altogether too many mine men think the dust on their roadways is not fine enough to be dangerous. He declared that in taking a 6-in. strip sample across any heading it is easy to get 4 lb. of dust fine enough to be explosive.

In coal that is without face planes, such as Pocahontas; as much as 10 per cent of the road dust will pass through a 200-mesh screen and therefore is most readily explosive and 20 per cent will be finer than 20 mesh, which is the Bureau's maximum size for dust that will participate in an explosion. In coals that show face planes, such as average Pittsburgh and Rock Springs coal, the percentages of fineness on roadways would be twice that of Pocahontas. Thus, according to Mr. Marshall, every mine is loaded with explosive dust, unless protective measures are taken, and the sooner the coal men of the country realize it, the better.

He said coal dust of 200-mesh fineness has no dimension greater than one one-thousandth of an inch and much of the roadway dust in the average mine has the impalpability of cigaret smoke. Hence the ease with

which it remains in suspension in mine air and hence, also, its readiness to propagate an explosion. In ordinary densities it will burn at a speed of 6,000 ft. per second, which is faster than ordinary powders, and as rapid as dynamite.

In the discussion that followed T. T. Read of the Bureau of Mines interestingly explained why fine coal dust is so inflammable. He said that coal dust in the air or on the roof, ribs and floor burns swiftly because the heat from each particle is communicated readily to the next particle. But if rock or adobe dust is present, the coal particles are separated from each other by barrier particles of non-combustible matter and the heat is absorbed by them. However, the rock or adobe must be of equal fineness with the coal if they are to be effective. Otherwise they would not remain in suspension with the coal and could not be present between coal particles when their presence was needed. Furthermore, this incombustible dust must be of a character that it will not absorb much moisture from mine air or it will become pasty, and thus ineffective. It must dry at the same speed as coal dust to avoid this separation from the coal. Few adobes will do this, so he places little confidence in adobe.

Eugene McAuliffe, president of the Union Pacific Coal Co., wanted to know whether it is essential to grind either rock or adobe to great fineness. If distribution of coarser adobe will do, the operator depending upon it to disintegrate in the road-

ways and get proper dissemination by the various stirring agencies, then his company would not go to the expense of installing a grinding mill. He got some comment on both sides of the argument, but the meeting came to no general decision.

Dan Harrington, now with the Utah Fuel Co. and the United States Fuel Co. in Utah, said ordinary adobe dust would do well without fine grinding in main intakes but that its character must be known definitely before dependence can be placed on it for moist mine interiors and return aircourses. Some adobe absorbs as much as 5 or 6 per cent of moisture out of mine air and therefore will not give satisfaction. Other adobe absorbs none. This type can be used without fine grinding, but when a mine does not have that kind of adobe it should use finely ground rock of some sort.

President Littlejohn said Utah had decided upon the use of finely ground limestone for barriers and for the dust zones nearby, but that adobe would be used elsewhere in Utah mines. W. D. Brennan general manager of the Phelps Dodge mines held that dry adobe is fine enough merely crushed. It does not have to be pulverized. Hand raking, ordinary travel and the other methods of periodically disturbing adobe dust in the mines at Dawson reduce its size and distribute it as effectively as though it were ground.

### DAN STARTS A DUST ARGUMENT

**I**S FREE silica in rock dust damaging to miners' health? All authorities in the coal industry have said it is and therefore all operators contemplating dusting their mines have felt that they must find a dust with practically none of it. Now comes Dan Harrington, one of the best known mining safety engineers in this country, telling the Rocky Mountain Coal Mining Institute that it is not so. He believes there is so little free silica in shale or rock dust that it cannot have any material effect on miners. Sharp-edged material ground down to 200-mesh fineness is so fine that it will not set up an irritation in the lungs, says Mr. Harrington. One dust is no more troublesome than another, he holds, and none of the fine dusts will cause trouble unless it is breathed in great volume. Average rock or adobe dusting of a mine would not produce this quantity.

His company takes it in from the streets and surface outside the mines. Only 10 per cent of it may be of 200-mesh fineness, but if any attempt were made to screen it, the real fines would be lost. So it is spread without screening. He pays boys 4½c. a sack to shovel it up at places where it appears to be finest. The cost of getting it to the mine is another 2c. This is much cheaper than grinding. Crushers would not work on adobe in wet weather, even if they were used.

Mr. Brennan believes barrier dust should all be of 200-mesh, but roadway adobe works well without any preparation.

#### WANTS LITTLE SILICA, CARBON OR WATER IN HIS

Capt. Jack Smith of the Union Pacific Coal Co. described the more or less well-known methods of dusting in Illinois, closing with a few conclusions of his own about dust. He advocates fine grinding, for it is his idea that only fine dust is efficacious. It should be practically free from silica, however, for the sake of the miner's health. It should have less than two per cent of combustible matter but in no case should it contain over 10 per cent. It should not be capable of absorbing more than two per cent of moisture from mine air and should be of light color to enable observers easily to determine when the slow admixture of coal dust with it begins to bring it to a combustible stage.

Fine grinding of any sort of material is cheaper in the long run, said Charles Leger of the Royal Fuel Co. He quoted John E. Jones of the Old Ben Coal Corporation of Illinois, a pioneer and close student of dusting, as saying that when dust is too coarse to be distributed by a blower, and is applied by hand, the cost is about \$12 per 1,000 lineal feet of entry, whereas blower dusting costs but 75c.

President Littlejohn thought a combined crusher and blower will soon be produced to do its crushing as it distributes the product. Thus none of the fines will be lost. Mr. Read had just remarked that he had seen most of the fine and really desirable dust escaping from a crusher in southern Illinois that tried to gather the pulverized material in a cyclone collector.

#### TILTING-BOARD BARRIERS UNDER A CLOUD

Reverting to the subject of barriers, Captain Smith said the so-called "concentrated barrier" once used in southern Illinois, made of a platform of wide planks each board tilting and dumping its dust in suspension when disturbed, was a failure. The boards warp slightly and do not trip when the trigger works. They are being replaced by steel construction.

At this point Mr. Harrington injected the opinion that the silica content of any rock dust is not a factor and should not be taken into consideration by the mine operator. The percentage of siliceous matter in any rock dust is so small and the quantity of rock dust in suspension in a mine is so trivial, at worst, that it cannot be any more injurious to the miners' health than coal dust or any other dust.

Mr. Read agreed that it would not be harmful in ordinary proportions after it was machine-applied, but that where dust is spread on roadways and stirred with rakes and brushes to get distribution, it might possibly be harmful if the silica content was high.

Then came a discussion about "mudizing." P. H. Burnell of the Lion Coal Co. described a machine his company is using at Wattis, Utah for the purpose. Adobe dust in water is drawn out of a tank by a centrif-

ugal pump, and sprayed on roof and ribs in a layer about ½ in. thick. The first coat washes down all the dust it encounters, penetrates everywhere and makes a perfect application at a low cost. The machine can coat about 1,500 ft. of entry in an hour.

Though it is true that coal dust and water will not mix, this adobe mud and coal dust will. A safe percentage of incombustible matter in the coal dust is certain, he said. It dries in 48 hours and thereafter, presents a surface that is dusty as chalk. The roof and rib surfaces offer little opportunity for coal dust to be deposited, and if roadways and faces are kept well sprinkled, he thinks, there can be little danger from coal dust.

"But that mudizing doesn't put much incombustible dust in the roadway," said E. H. Denny, district engineer for the Bureau of Mines. "How long will it take your mud to slough off a little and mix with road coal dust?"

"I don't know," replied Br. Burnell, "but mudizing is cheap enough to be applied often and if it is carried clear up close to the face and the mine is well sprinkled, there ought not to be much coal dust. It would be an absolutely dustless mine."

Mr. Denny remarked that it is next to impossible to get a mine perfectly clear of dust and that 5 oz. of fine coal dust per lineal foot of roadway is plenty to run a rip-snorting explosion.

*(Account of Rest of Meeting Will Be Published Next Week)*

ELECTRIFICATION GROWS at South Wales collieries. Great progress has been made recently in the electrification of the South Wales collieries, and, with the higher labor costs as a result of the recent agreement, a fresh stimulus has been given to the work of converting colliery power from steam to electricity. At the same time there is a great divergence of opinion on the question of central supply stations for a group of collieries. An instance of this is the total destruction of a central supply station at Ferndale, supplying power to eight collieries, which caused a shutdown of a month of all the pits involved. As a remedy for such a contingency it is proposed to interconnect a number of stations. Cardiff and Swansea are both increasing their generating plant for supplying electricity to collieries, and the output of the Cardiff City Station has more than doubled since the war. The local authorities at Newport, Bridgend and Neath are also augmenting their plants.

THE BUREAU OF MINES is conducting an investigation of mine wastes in relation to stream pollution. The investigation has been placed under the jurisdiction of Dr. Sayre, Chief Surgeon of the Bureau of Mines, in co-operation with the Public Health Service. It is being actively conducted by H. F. Yancey with headquarters at Pittsburgh. It is understood the investigation will require a year's time. Effort will be made to determine the facts as to pollution of streams by mines and remedies therefor with a minimum disturbance to the mining industry.

RECENT ESTIMATES of Utah's coal resources place the tonnage at 196,458,000,000 short tons. It is estimated that this is sufficient for the whole of the United States for 250 years. The state's coal mines employ 4,500 men regularly with an \$8,000,000 payroll.

## News Of the Industry

### Coal and Other Business Improving

Every Indication of Revival of General Business—Interest Rates Low—  
Increase in Tidewater Dumping—Law of Averages  
Would Indicate Hard Winter

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Indications of a decided revival in business were being registered throughout the past week in the central offices in Washington of the far-flung systems of fact and figure finding, which are maintained by the Government and by more than three hundred trade associations. More than the usual significance is attached to these returns, as the country with its abnormal gold reserve and with unprecedented capital to be had at interest rates which have dropped to a new low level, could burst into a boom almost overnight. The abundance of credit is indicated by the fact that the Federal Reserve system stands at 83 per cent, far above the 40 per cent margin of safety provided by law. The explanation lies in the fact that the banks are so well provided with funds that they do not need to rediscount their loans.

Though the improvement in the business situation has extended over several weeks, the psychology which is a necessary essential to any big upturn of industrial activity has just begun to crystallize. It is admitted frankly that with it are elements which well may lead to inflation.

Coal already has responded to the improvement in business, and is expected to reflect promptly the prospects of a Fall and Winter likely to be marked by great industrial activity. There has been a sharp increase in tidewater dumpings. This reflects the increase in industrial activity in New England and at other points which secure their coal supplies from the coastwise trade. Dumpings have been at a rate higher than any level reached since March and close to the maximum for the year. All rail shipments to New England have increased. There has been a gradual increase in the quantity of coal dumped at lower lake ports. The tonnage dumped thus far this season compares favorably with that of normal years. The movement up the lakes has been retarded because coal has been slow in moving off the upper lake docks, but indications now are that this movement will be rapid from this time forward and there is every reason to expect that the close of navigation will show that this trade has been equal to that of the average year. The better situations in the steel industry and in automobile manu-

facture are regarded as being of particular significance.

As no one expects the production of coal in 1924 to fall under 450,000,000 tons, production at an accelerated rate cannot be delayed much longer. As the railroads last year handled in excess of 10,000,000 tons of coal for a period of sixteen weeks, there is no serious talk of a car shortage. At the same time, it is admitted that circumstances easily could combine so as to make for transportation difficulties in handling the considerable volume of the year's production which is yet to move.

If a spurt in industrial activity should materialize, as the signs now indicate, and should Winter weather set in early, difficulties might be encountered. Weather bureau records show that an unusual amount of mild Winter weather has been enjoyed during the past seven years. No long-time weather forecasts are made by responsible persons, but according to the law of averages which has been established during more than the one hundred years for which records are available, the prospects are for a severe Winter. The unknown quantity in the problem is the quantity of coal in storage, but since that probably did not exceed 36,000,000 tons on Aug. 1, there is insufficient margin to carry industries long if they are to be called upon for increased outputs.

### Beckley, West Virginia—Next Objective of Union

John L. Lewis, international president, United Mine Workers of America, Ellis Searles, editor of the *United Mine Workers Journal*, Oral E. Garrison, organizer, C. Houck, international legal department, motored from Charleston to Beckley, W. Va., arriving in the afternoon of Aug. 7. An inspection was made of the headquarters of District No. 29, which property is owned by the International organization, and a conference held with several of those who have been identified with the United Mine Workers.

Being interviewed, Mr. Lewis had nothing to say, but Ellis Searles remarked that immediate steps would be taken to reorganize the district operating it from the Beckley headquarters.

### Another Merger Rumored

Rumors are rife but not generally credited that some of the larger smokeless concerns in southern West Virginia had recently been approached with a view of merging them into one big company. The companies named are the New River Co., Macdonald, W. Va., the E. E. White Coal Co., Glen White, W. Va., the Pocahontas Fuel Co., Pocahontas, Va., T. E. Houston interests of Cincinnati, Ohio, the Tams interests in the Winding Gulf region and the Wentz interests in the New River and Virginia fields.

### Industrial Conference Board Sees End of Slump

The business tide has turned, is the conclusion of the Mid-year Bulletin on industrial and economic conditions in the United States just issued by the National Industrial Conference Board. The board points out that although production and distribution during the first six months of this year have been below that of the similar period last year, it should not be forgotten that the first six months of last year witnessed the height of the trade boom. The report calls attention to the fact that the index of production in basic commodities as compiled by the Federal Reserve Board for the first six months of 1924 shows an increase over the average index figures for the years 1920, 1921 and 1922. From 1920 to 1923 inclusive the average was 94; for the first six months of this year the average was 111.

"During July, 1924, a considerable betterment in sentiment has taken place," says the report, "for although production has not increased considerably, prices are firmer and inquiries in respect to orders are more numerous. Trade sources indicate that June marked the low point in business so far this year, and that the turning point has been reached. The belief that business this Fall will be good is quite general. Exports for the first six months were 7.4 per cent greater in value than for the first six months of 1923.

The researches of the board show that at the end of the first six months of 1924, the cost of living was 61.7 per cent above the cost in 1914 and that amongst the items of this cost of living, rents were 85 per cent above the level of July, 1914, in June 1924.

## Disorder Threatens in Mines Of Western Kentucky

After three and one half months' strike in District 23, western Kentucky, during which period a few mines have resumed operation on a non-union basis, trouble has broken out in which a few workers have been beaten, shots have been fired into miners' homes, and miners have been threatened for failing to quit work. In one case an old lady who owned property rented to workers was threatened if she did not make them move. Not much had been heard of the condition until Gov. Fields and state military officials started an investigation in the field, and press reports started appearing about July 26 or 27 concerning trouble.

However, investigations have failed to show that there has been any real disorder, or need for calling out any state troops. Five or six observation officers of the Kentucky National Guard have made an investigation in the Providence, Ky., district, where are the mines of the West Kentucky Coal Co., and the seat of most of the trouble. That firm has been trying to operate some of its St. Bernard mines under the mutual or welfare association plan, which has proven satisfactory in the old West Kentucky Coal Co.'s mines.

### Lewis Speaks at Miners' Meetings

Conditions in the field were running along quite nicely prior to the visit of John L. Lewis, national president, to the field. Lewis talked before numerous miners' meetings. At the same time many autos from Illinois and Indiana entered the field, some bearing signs reading "Herrin," probably as a threat and not as declaring that the cars were from Herrin. Miners of the Norton Coal Co. have received intimidating letters postmarked "Herrin."

Outsiders have been working hard to hold the union miners in line, and stop the desertions to non-union ranks. Much of the mine labor in western Kentucky is negro, and this type is quiet, and generally causes little trouble. However, the negro when hungry, or without money and clothing, or gasoline to operate his flivver, is not especially strong for unionism.

Around Madisonville and Earlington it is claimed things have been quiet and

Utilities More Efficient  
In Use of Coal

Efficiency in use of fuel by public-utility power plants has increased 33½ per cent in the last four years, according to a statement by the Department of the Interior, which shows that a ton of coal in 1919 produced 625 kw.-hr. of electricity, compared with 835 kw.-hr in 1923.

The total amount of electricity generated increased in this period from 39 billion kw.-hr. to 55.7 billion kw.-hr. The statement said water-power development apparently is not holding its own with steam power in the production of electricity, showing a decrease from 37.5 per cent of the total production in 1919 to 34.8 per cent in 1923.

New York leads in the production of electricity, Pennsylvania is second and California third.

orderly, and at Central City there has been no effort to operate, and no excuse for any rough tactics. In the Providence section it is claimed that there are about 100 miners working non-union, and over 1,000 union men on strike.

### Alberta Strike Not Settled

The fourth month of the Alberta coal strike ended with July without any sign of a settlement. Efforts by the Labor Department of the Provincial Government to bring about a reconciliation between the miners and the operators have been unsuccessful. The Alberta government has no power to go further in the matter. Hon. James Murdock, Federal Minister of Labor, is expected to go West shortly and may take some action. William Sherman, president of District No. 18 U.M.W. of A., states that the miners are willing to meet the operators, on condition that there shall be no further effort to reduce the wages, but there is no indication that negotiations on this basis are likely to materialize. The loss to the miners in wages during the four months of the strike is estimated at approximately \$2,000,000.

## Ocean Carriers Revert to Use of Coal

The wide difference between the cost of fuel oil and the cost of coal is resulting in the reconversion of many ocean carriers to the use of coal. This was one of the significant trends which Dr. George Otis Smith, the Director of the U. S. Geological Survey, observed in Europe. Dr. Smith has just returned from London where he represented the Secretary of the Interior at the World Power Conference. Another development which has much significance for coal he points out, is the progress being made in the production of a liquid fuel with coal as the base.

"A power conference held in Great Britain," declares Dr. Smith, "naturally puts emphasis on coal. As I mentioned at one of the sessions of the World Power Conference, commerce in power already is an international matter. When consideration is given to the number of wheels, throughout the world, that are turned by British coal and by American oil, there is a greater appreciation of that fact. I saw electrical energy derived from British coal and from Swedish waterfalls at work in connection with the operation of Danish farms. This example is typical of the use of power which takes on an international character.

"I saw evidence that British shipping, at least, is trending away from oil as a marine fuel because the cost of coal is relatively so much lower. The price level of fuel oil was characterized as being 'totally unwarranted.' I was told that fuel oil was selling at Mediterranean ports at 87s. 6d. (\$19.93 present exchange) per ton as against 35s. (\$7.97 present exchange) for coal. Bunker coal was obtainable at United Kingdom ports, I was advised, at 20s. (\$4.56). Some oil-burning ships already have been reconverted to coal. Apparently this is prophetic of what surely will take place more generally at some time in the future unless economic processes are developed for using coal as the source of a liquid fuel.

"It is significant that so strong an interest as The Vickers is giving attention to processes for treating coal as the raw material in the manufacture of fuel in more convenient forms."

### Opening Gun in Plan to Increase the Safety of West Virginia's Mines

Open lights are doomed in the soft-coal mines of West Virginia, judging by a consensus of the opinion expressed at the safety meeting held in Fairmount, that meeting being one of a series called by the West Virginia department of mines for the purpose of obtaining suggestions as to sections to be incorporated into a new mining code for West Virginia. Mining men now are generally a unit in expressing the opinion there are no non-gaseous mines.

R. M. Lambie, chief of the West Virginia department of mines, said the open-flame lamp must be discarded. He regards that as the first precaution to be taken in guarding against serious accidents. Mr. Lambie cited several instances to show that some mines that had apparently never emitted gas had shown themselves gaseous after a slate fall. "It's not what you have, but what you might have," remarked the head of the department in summarizing the great danger which at all times was to be feared from gas in soft-coal mines.

#### More Speed for Bureau

Frank Haas, consulting engineer of the Consolidation Coal Co., said that some means should be used to get the U. S. Bureau of Mines to speed the process of testing and approving of machinery for use in the mines. He urged that it might be advisable for mine operators to let manufacturers of mining equipment know that approved machinery is in demand.

A practice greatly condemned by Mr. Lambie was the shooting of coal from the solid. V. G. Deahl of the Hiorra Coal Co. said that this practice was common in his field, attributing such violations to the loose practices which prevailed during the war.

#### Might Change Machines Over

Chief Lambie stated that although he wanted reforms in the state mining laws, it was not the desire of his department to force coal companies to put in approved equipment in the mines immediately, providing that they add safety devices to the present machinery.

E. P. McOlvin, of Clarksburg, stated that the state mining law should define the meaning of "shooting coal from the solid." Dean R. C. Jones, of the school of mines of the West Virginia University, suggested that a blank be issued by the department to be filled out whenever gas is found. He recommended that this be incorporated in the reports of the mine foreman and fireboss.

### White Will Head Coal Commerce Division

C. P. White, formerly in charge of distribution for the U. S. Fuel Administrator, will head the coal division of the Department of Commerce, a position that has been vacant since the resignation of F. R. Wadleigh. This place was offered to Mr. White at that time but just then he was not in position to accept it. Secretary Hoover felt the place well might be left vacant until a properly qualified man could be found. He also was influenced by the fact that the coal division was in the capable hands of F. M. Shore, who was Mr. Wadleigh's assistant and who has been acting chief since Mr. Wadleigh's resignation. Mr. White served as an assistant to Mr. Wadleigh while the latter was Federal Fuel Distributor. At that time Mr. White was in charge of the situation at the head of the Lakes.

### Dock Men Counter Attack In Northwest Rate Battle

The Northwest Dock Operators Association and other dock interests on Aug. 1 filed with the I.C.C. at Washington an answer to the various petitions that have been filed against the Sept. 10 increase in rates on Illinois coal going into the Northwest. The answer appears especially to be a reply to the long attack the Illinois Coal Operators' Association made two weeks before, in which they pointed out many commission errors and appealed for a reopening of the lake dock rate cases which they had lost.

In the dock men's reply, the Chicago law firm of Butler, Lamb, Foster & Pope declares that the so-called "errors" were not errors at all, that Illinois does not show that it has any new evidence to present which would be worthy ground for a reversal of decision by the I.C.C. and that therefore, there is no reason for a reappearing of the cases. The dock answer denies that the Commission based its decision on the fact that tonnage from the docks to the Twin Cities had declined while Illinois tonnage increased. This had nothing to do with the decision. It denies that the decision is illegal simply because the changes ordered will require other readjustments under the long-and-short-haul clause. Righting one wrong is not illegal merely because it does not right all the wrongs that exist.

#### Answer Justifies the Commission

The answer further holds that the evidence in the case proved that the same carriers control rates from both rail and lake territories of origin, and therefore the Commission was fully justified in removing the discrimination that existed. It held that the Commission did not err in making its order apply only to certain groups and not to all Illinois groups because the original petition omitted many. It contended, also, that exclusion by the examiner of evidence with respect to origination of dock coal in the Appalachian region was not erroneous because the dock rates are local rates.

### Canada Shares in Our Slump

The output of coal from Canadian mines during May declined to 708,004 short tons, being a decrease of about 30 per cent below the tonnage of the previous month—and the lowest point reached since April, 1923. The falling off was due to the Alberta strike and the lessened output of Nova Scotia owing to lack of orders. Production in Nova Scotia fell from 640,000 tons in April to 430,000 tons in May. There was a marked increase in the importation of coal from the United States and Britain, May imports amounting to 1,105,126 tons, as compared with 734,991 tons in April. Exports of coal were 47,905 tons in May as against 5,318 in April. The number of men employed in the coal mines in May was 20,007, the monthly production per man being 34.3 tons as against 48 tons per man in April.

### Old Ben Selling \$13,000,000 In Bonds and Debentures

Prominent among recent industrial financing is the issue of \$13,000,000 securities by the bankers on behalf of the Old Ben Coal Corporation. The offering will be made today of \$8,000,000 first mortgage twenty-year 6 per cent gold bonds and \$5,000,000 ten-year 7½ per cent debentures.

The \$8,000,000 issue is being offered by a syndicate consisting of the National City Company, Drexel & Co. and Cassatt & Co., at a price to yield over 6.17 per cent. The \$5,000,000 debentures are offered at 100 and interest by the National City Company and Cassatt & Co. The twenty-year bonds are secured by a first lien on all the mineral and surface lands, real estate, mine plant and equipment and other fixed assets of the corporation. For the debentures provision has been made for a semi-annual sinking fund commencing Feb. 1, 1925, sufficient to retire by lot \$250,000 par value of the debentures annually at 110.

The Old Ben Coal properties are in southern Illinois and include 56,800 acres of coal land. The average annual net earnings after depreciation and depletion, according to the bankers, are more than five times the annual interest charges on the \$8,000,000 of first mortgage bonds. Current assets are more than six and a half times current liabilities. The company is making extensive improvements.

## Practical Pointers For Electrical And Mechanical Men

### Should the Positive Conductor from a Mine Generator Be Grounded?

Direction of Current Usually Presents No Serious Problem—Standard Practices Should Be Followed to Simplify Conditions—Uniformity of Connections Reduces Hazards

A MUCH debated question at a certain mine in our neighborhood is whether it is safer and more efficient to transmit direct current from the power station into the mine and to various other points in and around the plant with the trolley wire connected to the positive or to the negative lead of the generator.

Let me outline the conditions at a plant to which I refer. Power is generated by a compound-wound direct-current generator at 250 volts. The current is led from the positive brush stud on the generator to a positive switch on the switchboard and from this board to the positive busbar. All mine tracks and other parts of the usual electric circuit were connected to the positive busbar at the switchboard. With this method of connection it is obvious that pipe lines and steel structures were being utilized as positive conductors and all feeder and trolley lines used as negative conductors.

The following questions arise as to the safety and efficiency of this system of transmission:

Question A—Does this system of transmission of an electrical current tend to create more or greater hazards to the workmen in or around the mine? Are workmen more or less likely, through grounds or other causes, to receive shocks with this system? Are the hazards of the accidental starting up of any electrical machine or device increased?

Question B—Is the fire hazard increased by this system? Are the pos-

sibilities of an explosion from coal dust or mine gas increased? Will current leakage produce more, or less, electrolysis?

Question C—Will the efficiency of the generators, motors or other electrical apparatus be impaired in any manner?

Question D—Will lightning arresters work effectively on this system?

Question E—Is the potential of the positive wire of this system at the earth's pressure, there being 250 volts pressure between the positive and the negative wires? Is the negative wire at a potential 250 volts below the earth's zero pressure?

THOMAS BRENNAN.

Bairdfield, Pa.

It is the usual practice at mine operations to connect the negative wire from the direct-current generator to the ground. The best results are usually obtained by making a direct connection to the mine track at a point as close as possible to the generator. However, so as not to depend entirely upon this connection to carry all the return current back to the generator, negative conductors are often run far into the mine.

These ground connections are as important as the feeder lines, because it is necessary to keep the return circuit resistance as low as practicable so as to have good voltage at distant points in the mine. All current going through the machines used on direct-current circuits must pass through the motor windings and return to the generator. Wherever the current meets an obstruction, usually called resistance, a certain quantity of energy is lost in order to get through.

With most electrical apparatus it matters little whether the current travels in one direction or another; in fact, trolley locomotive motors are continually being reversed. The current flows in one direction continually only in those parts such as the trolley pole and sometimes the resistance, depending upon the connections used in the control wiring.

Some people have a false idea that only positive electricity does any work or can do any harm. This is not true. If the negative wire at the generator is

grounded, to stand on the ground and touch a positive trolley wire causes the current to flow downward through the body to the ground. On the other hand should the positive conductor of a circuit be grounded and the negative connected to the trolley, a person standing on the ground still gets a shock when he touches the trolley wire, but the current passing through his body travels upward through his feet.

The essential thing to remember is that current passes in one direction or

Negative Connection to Trolley

With a connection like this at one mine and the positive lead of the generator connected to the trolley at another mine it is possible to get a high potential difference between the two trolley wires at points where the systems come close together and thus create a hazard because of the high voltage.

another whenever a circuit is closed between the positive and negative leads of the generator. Unless this is done the current cannot flow. Consequently a person may handle or tread on any one of the two leads coming from the generator if he does not come in contact with the other conductor at the same time. However, such a practice is not advisable because the other conductor is not always apparent, it may be grounded or accidentally connected to some conducting material nearby and to touch this material while connected to the other wire would be equivalent to touching the other conductor direct.

The hazards due to grounding the positive wire from the generator and connecting the negative lead to the trolley are not great. As it is not the usual practice, a person working around a motor may test a certain wire and find it to be the negative lead and therefore feel quite safe in handling it, if he has been used to working in mines where the negative wire is grounded. Trolley wheels running against the trolley wires connected to the negative terminal of the generator usually sputter and throw off sparks more profusely than those running against positive trolley wires. Aside from these two hazards there are no further serious dangers.

If a negative trolley wire or feeder is given the same protection and care as a positive trolley or feeder the dangers are no greater from one than

Standard Generators and  
Trolley Connections

Sometimes the series-field end of the generator is made the positive terminal but connected to the trolley wire. This is done where the trolley wire is exposed to lightning in which event a lightning stroke generally breaks down the series-field winding and does not reach the armature. The series field winding is easier to repair than the armature.

the other. Accidental grounding of a negative trolley wire acts in the same way as an accidental grounding of a positive trolley; it closes the circuit on the generator. The same is true with the accidental starting of motors. The same conditions which will cause a motor connected to a positive trolley wire to start causes a motor connected to a negative trolley wire to start. The only difference is the direction in which the current flows.

The fire hazards are the same for both conditions because it usually matters little in which direction the current may be flowing. The spark is formed regardless of the direction of the current. If the voltage is high enough to create a spark, which is certainly true with a 250-volt circuit, gaseous mixtures or dust may be exploded.

However, electrolysis does depend upon the direction in which the current travels. Currents passing between two electrodes carry the metal of one over to the other. By reversing the direction of the current the metal which is the harder to break down may be carried away and in consequence the electrolytic action may actually be reduced. However in most mining work the seriousness of electrolysis asserts itself in connection with pipe joints and usually the damage done would be about the same regardless of the direction the current may be flowing through the pipes.

The efficiency of the generators or motors is not changed by reversing the flow of current. Many generators and most motors are designed to operate in either direction, and the reversal is

accomplished by changing the direction of the current in some part of the winding.

Lightning arresters are installed for the purpose of draining conductors of any abnormal voltages, and they will discharge just as soon as the potential difference between the two ends of the arrester increases to a sufficiently high value. The action of an arrester connected to a negative trolley wire is the same as with a positive trolley wire; it merely drains off to the earth any abnormal voltage on the conductor.

Any conductor directly connected to the earth takes its potential, because it then becomes part of what we call "ground." Pressures may be above or below the potential of the earth. Ordinarily the pressure at the earth is considered as zero. It does not usually matter much whether a potential is higher or lower than zero, the important fact is the volume of the difference of pressure between objects. As the pressure in the negative conductor of a 250-volt circuit is 250 volts below that in the positive wire, if the positive wire is grounded, the negative conductor has a potential difference of 250 volts between it and ground. In this case the voltage will have a negative value with respect to the earth.

These answers to the foregoing questions deal with the subject in a general way. Under certain peculiar conditions one system of generator connection is better than another, but usually it will be found best to connect the positive lead of the generator to the trolley and thus conform to the recognized practice.

much dirt and grit is encountered as in cement mills, brick plants, flour mills, or crushing plants. It is an excellent belt for use in hot and dry places. It is strong and durable, but must never be used in connection with finger shifters because such shifters wear the edges rapidly, causing them to fray.

There are a number of rubber composition belts on the market, and it is claimed by many users that these are superior to leather belts. It is my belief that the rubber belt is superior to the leather belt for use in wet or damp places. In fact, it has practically replaced the leather belt in all such places. Like the cotton belt, however, it must never be used in connection with finger shifters because it has a fabric core which will cause failure if the edges are once worn or frayed.

The life of a belt depends largely upon the start it gets, in the same way that the success or failure of a man depends largely upon the care given him during his childhood. Therefore, when putting a new belt on the pulley too much care cannot be given to it to see that it is put on correctly.

Shafts and pulley should be aligned as perfectly as possible so that there will be no side slipping, no forcing, no running off and no side pull.

Occasionally there is something inherently wrong in the belt itself so that after a few days of operation it will run crooked in spite of the care first given it. This may be due to the fact that one side of the belt was stronger

than the other, consequently the weaker side stretched most, and as a result the belt began operating imperfectly. When this happens the belt should be taken off and the imperfection carefully removed. Unless this is done it is obvious that there will always be some side slip or side pull and the life of the belt will be materially reduced. It pays to watch new belts carefully and see that they get a proper start in life.

It is impossible, of course, to answer the above question completely and with absolute accuracy, but the writer feels that his reply is at least more definite and more satisfactory than the reply given by the dealer.

W. F. SCHAPHORST.

## Taking Taps Off Transformer For Lighting

At one of our transformer banks, consisting of two 25-kva. single-phase transformers connected in open delta, we desire to take off taps for supplying a lighting circuit. It has been proposed to connect the lighting circuit to use one half of each transformer winding. Will this connection work and give satisfactory voltage for 220-volt motors at the same time? The accompanying sketch shows the transformer connections.

St. Charles, Ky. C. E. ANTHONY,  
Dempster Coal Co.

Two transformers connected in open delta cannot be loaded so as to carry a load equal to the arithmetical sum of their individual capacities. For example, two 25-kva. transformers may be loaded safely to 44 kva. Care should

## Open-Delta Connected Units Supplying Lights

With this connection the transformers are arranged to supply 220-volt energy to a motor circuit and 110-volt energy for lights. Care should be taken when using this connection because the individual transformer windings are not uniformly loaded and may cause local heating.

therefore be used when transformers are connected in this manner.

A discussion of this subject was given in the July 10 issue of *Coal Age*. Here O. E. Kenworthy explains in detail the operation of the transformers.

The voltages supplied by two single-phase transformers connected in open delta will be balanced but care should be taken when using parts of the transformer windings for other loads. If the circuit shown in the illustration is used for lights the loads in the transformers are unbalanced and one section of a transformer winding will be working under a heavier load than the other. This may cause local heating, which depends upon the particular design of the windings.

## What Kind of Belt Should Serve My Purpose Best?

A belt user recently wrote to a dealer in belts and asked: "What kind of belt is the most economical in the long run?" The dealer replied: "The belt that will transmit the most power per square foot of its area during its natural length of service is most economical."

This answer may be correct. In fact, it is correct. But, now that the belt user has the answer what is he going to do with it? The answer is certainly a vague one. Very likely the user knew that much about it before he asked the question. What the user wants to know is, What kind of belt is the most economical in the long run—leather, cotton, rubber, camel hair, balata, etc.?

In spite of all the substitutes that have been manufactured, leather belting is still quite popular. It is the superior belting for general machine-shop work. Where belts must be shifted from pulley to pulley there is nothing better. In fact where finger shifters are employed nothing but leather belts should ever be permitted. Leather belts are also superior for use on quarter-turn drives, reversing drives, or wherever there is constant side pull, slipping, jerking, etc.

The cotton belt to a great extent has replaced the leather belt for power transmission on machines used out in the weather. Likewise it has replaced the leather belt in industries where

# Production And the Market

## Bituminous Coal Market Feeble but Reviving Anthracite Trade Slow and Weakening

If the revival of the coal trade does not come soon it won't be for lack of prophets and heralds. From reports one would think the bituminous-coal producer was anxious for a revival of his industry, but the truth is that the coal men are divided in sentiment. They don't like the present slackness. Who would? But they also realize that the longer it lasts the surer will be their reward at the end. If the market were to brisken now, the volume of business would increase, but it would not be profitable business. If it waits a few months more it will have not only volume but profit, not only current strength but voltage also. However, to have to wait is vexatious and it looks now, despite the Geological Survey's report as of August 2, as if a gentle increase in production will soon be on its way. Every-one forecasts either that or a wild market, and in a few places here and there a little improvement in the coal trade is manifest. The big fall trade, and the winter anxiety about fuel which has been prophesied will hardly come, unless someone whose opinion is recognized starts something and the public in a panic does the rest. It is more likely we shall see volume rather than profit. The public has so strong a hold on the situation that the coal man has to admit that the industry "functions badly" as far as his profits are concerned. However, if the indications of increased business—and there are but few of them—are illusory and the public continues to wait, the awakening may not be pleasant.

It is useless to consider the markets separately for they conform too closely to type. Something might be said as to the Great Lakes. There only a certain dock-age space is available and the unwillingness of the retailer to buy has cluttered the docks with coal. The Northwest does not have as much time as the rest of the country to satisfy its wants, so it would do well to get coal moving.

Coal Age Index of spot prices of bituminous coal

showed no change during the past week, standing on Aug. 11 at 163, the corresponding price being \$1.98.

Hampton Roads dumpings for all accounts during the week ended Aug. 7 totalled 358,916 net tons, a decrease of 3,084 tons from the week preceeding.

The movement of coal at the Lakes made a marked decline, being for the week ended Aug. 10, according to the Ore and Coal Exchange: For cargo 725,168 net tons and for fuel 47,054 net tons, as against totals of 830,915 and 44,066 net tons respectively the week before.

The production of bituminous coal for the week ending Aug. 2 decreased slightly, the output according to

the Geological Survey totalling 7,486,000 net tons. The previous week showed an output of 7,542,000 tons, according to the revised figures. Anthracite production decreased, being 1,720,000 net tons in the week ending Aug. 2 and 1,837,000 tons in the previous week.

The anthracite and bituminous coal markets, strange to say, are in a similar condition. Both are feeble, but whereas the anthracite sales are few but declining, the bituminous sales are few but increasing. Canada is still a weak market for anthracite. Winnipeg seems to be responding to the active efforts of the Alberta producers who are supplanting those of Pennsylvania.

### Midwest Sells Little for Storage

The midwest shows a little activity in a small way in the higher-grade coal for storage purposes, but nothing doing in anthracite, smokeless or coke. Medium Illinois coals are slow.

The warm weather during the past week is largely accountable for stopping of domestic orders. With no apparent increase in price the public is indifferent yet as to any great movement of storage. Wagon-load steam is at a standstill and carload steam is easy and not noticeable.

There is practically nothing doing in Southern Illinois although a little coal moves occasionally, but the tonnage seems to be dropping off except in spots. There is no great movement of any one particular size in the Carterville field. All mines have unbilled coal of all sizes, including steam. Railroad tonnage is light. Mines get from one to three days a week. The strip mines still continue to show good working time.

The Duquoin field is near at a standstill and the Mt. Olive district is about as quiet as it can be. A little railroad coal is moving out of this district and some small tonnage on contracts.

The Standard coal field is tied up with no-bill coal of all sizes. Screenings continue to go down, and the domestic sizes show no increase, excepting in 6-in. lump, which has moved up 15c. this week. Every kind of coal is lagging in a disheartening way. Railroad tonnage is off.

Chicago had a keen disappointment last week as business showed a notable slump. It is thought that previous activity was due to optimistic newspaper reports of farmer prosperity and a booming stock market. Evidently the coal market is to be left behind in the new prosperity.

### Kentucky Still Hopeful

Somewhat better demand for fuel is reported in the Louisville market. Domestic sizes are moving better, as the public is beginning to think about winter supplies, and better agricultural and general business conditions are resulting in more confidence, especially among wage earners. Retail prices have been firm since the April reductions, and it is generally understood that the market can move only in one direction and that is upward. Retailers are still slow in stocking, from fear of summer slacking, heating, etc., and because collections have been slow, and they do

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	Aug. 11	Aug. 4	July 28	Aug. 13
Index	163	163	163	196
Weighted average price	\$1.98	\$1.98	\$1.98	\$2.37

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

not want to tie up capital in stock. A lot of retailers are unable to see anything in sight that can force the market up.

Slightly firmer prices on 6-in. block coal and improved demand for prepared sizes marked the week in Western Kentucky. Some operators are now quoting a low of \$2.25 on block, and as high as \$2.50, as against a market of \$2.15-\$2.35 a week ago, although some block can probably be had at right around \$2. Egg, lump and nut prices are unchanged. Illinois Central R.R. mines favored by railroad buying, and fair movement of mine run, have been asking as much as \$1.85 for good qualities, but some strip pit coal, and off-grade stuff in the field can be had at \$1.40 and probably less.

### Northwest Has One Bright Spot

Everything is better at Duluth than at last writing, with trade brightening, more shipments going out from the docks and prices firmer. There has been no change in prices during the past week, but it is expected by the dock men that an increase will take place within a short time in bituminous coal if trade continues active.

The Twin Cities are awaiting the harvesting of the crop before purchasing anything. Both consumers and dealers have thus far bought much less coal than they should.

Dock receipts have been much less than a year ago, but the dock men carried over so much coal that they have about as much on hand as they had a year ago. They do not want any excessive tonnage and hope producers will not load them excessively.

August weather is not conducive to coal buying, never-

theless Milwaukee dealers say there is a slight improvement in the demand. The demand is bound to increase, now that the fall months are approaching. A general revision of prices of soft coal is anticipated Sept. 1, in addition to the final increase of 10c. per ton on anthracite. Cargo receipts to date aggregate 405,438 tons of anthracite, and 1,022,088 tons of soft coal.

### Southwest Made Stumbling Start

A few weeks ago Southwestern operators, encouraged by a steadily strengthening demand, thought they saw an early fall market. Since, the market has weakened until in the early days of August less business was done than in the same period of June. Some operators, who had announced their intention to advance their quotations on Arkansas semi-anthracite Aug. 1, were deterred by the decline. Schools have begun to store for winter and there still is a light demand for threshing, but, with the exception of the normal industrial contract market, this is the extent of demand. Henryetta, Okla., coal is \$4.50 for lump, \$4 for nut, \$3.75 for mine run and \$2 for screenings. Arkansas semi-anthracite is quoted from \$5.50 to \$7 for lump, \$3.50 to \$4 for mine run and \$2 for screenings.

In Colorado the sales of domestic coal improved a little last week. Storage orders are beginning to come in but only slowly. Although conditions are far from encouraging and normal, operators are fairly optimistic for they are expecting to have a busy month. Mines worked on an average of twenty hours with 49 per cent of the working time lost attributed to lack of market.

### Cincinnati Better but Doesn't Know It

In Cincinnati the trade spirit has sunk to the lowest ebb in years, the weather probably being the cause. The buyers' market still continues with scarcely an item in the whole list being actively sold. Yet production has shown an upward trend. The figures of J. A. Morris, in charge of car interchange for the West Virginia-Kentucky coal section under the American Railway Association, shows 9,849 loaded cars passed north at the gateways under his jurisdiction, an increase of 402 cars over the previous week. Lake movement is still low, the number of cars due there being 21 less than during the preceding week.

Run-of-mine prices have stiffened again. Buyers find that \$1.40 is about the lowest price at which good coal can be obtained. Some steam stuff is still obtainable around \$1.25, the malleables and byproduct coals run higher, some quotations being as high as \$1.65-\$1.75. Domestic business is "shot" and the slack turnover is about grooved at 75c.-\$1.10.

In smokeless there is little disposition on the part of the standard Pocahontas producers to slice the price named by the circular. Some New River prepared in lump and egg can be had around \$3.75, though seemingly there is an absence of the \$3.50 coal that could be had last week. The screenings are draggy, the asked price running \$1.25-\$1.50, and where large tonnages are involved the price is shaded. Specialized coals are selling: Egg \$2-\$2.60; lump \$3-\$3.50.

In a retail way there was a fairly healthy swing into August, with prices lined up this way: Pocahontas lump \$8, run of mine \$5.50-\$6, bituminous lump \$6.25-\$6.50, slack \$3.50-\$5.50.

Better feeling is developing in Columbus and central Ohio territory. Buying of domestic sizes has increased slightly and producers as well as jobbers believe that a much stronger demand will soon come from retailers. Retail prices are fairly steady at the levels which have prevailed for some time.

Steam trade is still dull and there are no indications of improvement. Railroad requisitions are not especially large. Iron and steel plants are only buying what is needed and there is no general movement to stock up. Utilities are the best customers. School coal is moving in large quantities and municipalities are also placing orders.

A seemingly stronger demand for slack and screenings has stiffened the spot prices of these grades in eastern Ohio from 5 to 20c. per ton. Less slack is available for the Lake shipping from No. 8 field has demanded less lump than usual and consequently the mines did not produce the slack. The market for Lake cargo coal is very quiet.

In other ways also, the general tone in the coal trade is better, but appreciable improvement is, of course, being

retarded by the general depression. During the week ended Aug. 2, the No. 8 field of eastern Ohio produced 266,000 tons, or about 38 per cent of the estimated capacity of the field for the week. This was 11,000 tons under the output of the preceding week and 161,000 tons under the corresponding week of last year.

The Geological Survey reports continue to show increased shipments of coal from the general Pittsburgh district, say a 30 per cent operation against about 20 per cent in April and May. The trading market in coal does not reflect any such increased activity, though it is now probably a little less dull than in April. Such increases as there have been in shipments probably have been due chiefly to heavier movement between operators and regular customers, those who ordinarily have contracts for the coal year, but now simply take shipments as they need them and adjust the price periodically.

The bituminous coal trade in Buffalo is quieter than ever. Only the slow condition of other branches of trade keeps some dealers from giving up their coal business altogether. They are beginning to fear the old bituminous-coal market in Buffalo is weakened forever, the non-union fields ousting the union and going to the consumer by other routes.

### New England Prices Stiffening

The bituminous situation in New England has improved a little during the past week. Actual purchases have not been any larger—in fact total sales are probably slightly less owing to decreased activity due to hot weather—but the sentiment is better. Many consumers, some of them large, have announced that they must come into the market shortly.

Prices have assumed a healthier tendency during the last day or two. Offerings of good low-volatile smokeless are less frequent at \$5.40 gross ton on cars, Boston, the going figure last week. Where this price was acceptable a week ago \$5.45 is now the bottom, and certain shippers here who sell on a guaranteed analysis hold firmly for \$5.50 on cars whether one car or a dozen is ordered. This firmer tendency follows news of a decline in tonnage at southern loading ports which is expected to be reflected shortly in spot f.o.b. prices.

The industrial situation has taken a turn for the better. Shoe factories and textile mills have greatly increased their running time. Water is low, and coal must be used for steam making. Pennsylvania still finds a narrow market, due to the margin in favor of landed tidewater coal prices. Coal has been shipped from Boston to a fairly northern Vermont point that is normally all-rail territory, at a landed cost over 25c. per ton lower than that of a like quality Pennsylvania coal. Sales of Pennsylvania coal are largely confined to retailers and consumers who desire lumpier coal than New River.

### Atlantic Seaboard Situation Improving

In the New York bituminous market many wholesalers report improvement. More inquiries are reported and a greater demand for tonnage, though, of course, a number of unfavorable factors continue and certain unethical practices are uncovered from time to time, such as operators quoting lower prices to consumers than to wholesalers which, of course, makes an unfavorable impression on those who have so often borne a burden on behalf of the operating interests. There is as yet no change of consequence in prices and little is anticipated in the near future.

At Philadelphia the soft-coal trade is as inactive as last

week, but the iron and steel trade shows signs of distinct betterment, with some plants already operating on a larger scale and others preparing for increased activity. As yet the buyers for these concerns are proceeding cautiously in their coal purchases and as a result the coal market has not felt any impetus.

Business is dull in Baltimore. The failure of the early August market to strengthen is reflected in price quotations, which are about the same as they have been for the past several weeks. Exports for the first eight days of August show a decided falling off as compared with the same period of July.

A better feeling prevails in the Birmingham trade, a more active demand for coal being exhibited than for several months past. Contracts have been made by consumers who for some time have been supplied from the spot market. A little more spot business was booked than in the previous week, and bunker demand was slightly better. Small towns and community centers are placing orders for domestic coal in one- and two-car lots. Further wage reductions are reported at some commercial and domestic operations.

### Some Anthracite Mines on Short Time

In New York traders in anthracite feel much encouraged by the increased number of inquiries of the past week. So confident is the belief in approaching better conditions that middle-houses are limiting their commitments, not caring to have too much business booked at present prices.

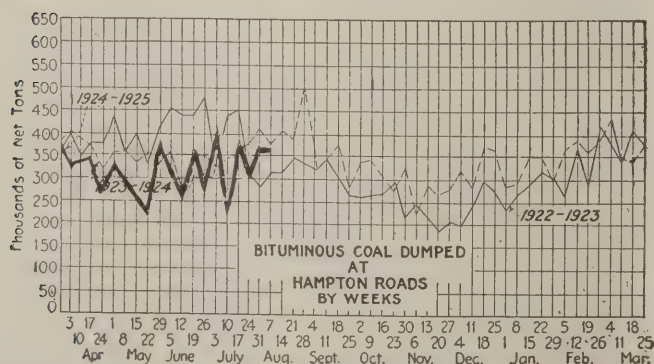

Stove coal continues strong, and egg, as usual, is in second place as regards demand, nevertheless it is holding up remarkably well. Chestnut moves sluggishly, but the revival in the western trade is expected to cure this. Buckwheat and rice are in a somewhat better condition. Barley also has been moving well considering the low price of bituminous coal with which it has to contend.

The demand for anthracite in Philadelphia is so light that some operators last week put their mines on a four-day schedule. This plan will be followed in the coming week. In consequence no large-sized coal will be stored by the producer for winter demand. The only size the retailers want is stove, and they are content to wait till it comes. A small tonnage of nut and pea are sold occasionally at reduced prices with \$8.75 and \$5.25 as their respective prices. Steam coals are rapidly accumulating. The independents are known to be moving some of their surplus buckwheat at \$2 to \$2.25 with proportional cuts on rice, although barley is not so difficult to sell.

Despite the effort to get their customers to buy by prophecies that coal will advance at retail 25c. per ton on the first of September, Baltimore retailers are finding trade extremely light. In New England the retail anthracite demand shows further contraction and the wholesale market is dull with marked irregularity in independent prices.

The Buffalo anthracite trade is slow. Anthracite which gained when the natural-gas flow began to subside is losing business now to the gas from big byproduct ovens.

The Connellsville coke market continues dull. The decrease in blast-furnace activity practically ended several weeks ago, and coke production has lately been closely adjusted to requirements, so that there is neither distress coke seeking sale nor consumers seeking extra tonnages. The furnace coke market has been quotable at \$3 for several weeks. Foundry coke remains at \$4 to \$4.50, to which it recently declined. Demand if anything is a shade lighter than a fortnight ago. Heating coke remains quotable at around \$2.60 to \$2.75, with good medium sulphur coke, for non-ferrous use, at say \$2.75 to \$2.85.

# Foreign Market And Export News

## Coal Trade in Great Britain More Depressed than Ever

The Welsh steam coal market is inactive and depressed, and, though a number of pits have been closed down, production is still ahead of demand. With few exceptions the collieries are accumulating stocks, and notices to terminate contracts have been given at several collieries affecting about 6,000 miners. The threat of the Miners' Federation to strike in the Rhondda No. 1 District on the non-unionist question appears to have been effective, as nearly every non-unionist has been brought in.

Business all round is poor, and prices show a tendency to decline still further. European business is well below the average, France and Italy taking very little coal of any sort. Only occasional orders come from Belgium and Germany.

The Newcastle market is also depressed, inquiry is slow and small in volume, and many of the pits are finding it difficult to keep going steadily. The industrial demand is at a low ebb, though operators are hoping for a revival in gas coal contracts on account of storage for the winter. The Palermo gasworks have contracted for the supply of about 12,000 tons of gas coals for delivery during August and September.

Production by British collieries during the week ended July 26, according to a cable to *Coal Age*, totalled 4,489,000 tons, compared with 4,904,000 during the week ended July 19.

### France Has Shortage of Domestic Coal

Industrial coals are inactive with increasing tonnages offered. On the other hand there is a shortage of domestic coal and consequently a market favorable to the coal operator. The coal companies are behind with their orders and in cases were shipping coal in the end of July that they should have forwarded in May. In British

coals, transactions are relatively slow. It is reported that large French purchasers have recently been concluding contracts for British coals with deferred

deliveries. For instance, the Midi Railway Co. has, it is said, just purchased Durham coking coals that are to be delivered early next year.

On the other hand, in French channel ports no British coal has been received by central stations for two months. No complaints have been heard this week relative to the lack of rolling stock.

From July 1 up to July 15, France and Luxembourg received from the Ruhr 206,100 tons of coal, 282,900 tons of coke and 11,300 tons of lignite briquets or a total of 500,300 metric tons. In the Ruhr the increase in the length of the working day has increased production, but sales are not responding to that increase as German coal prices in gold marks are still too high. Idle days are contemplated in the Ruhr.

## News Items From Field and Trade

### ALABAMA

Suit for \$100,000 has been filed by C. L. Moss and G. B. McCormack, Jr., as individuals, and as Moss & McCormack against the Jagger Coal Co., John Gray and E. P. Rosamond, Jr., as damages for alleged conversion of coal.

At the sitting of the board of mine examiners held in the offices of Chief Inspector C. H. Nesbitt, July 21-24, fifty-seven applicants took the examination for certificates as first and second class mine foremen and fire boss, thirty-six of whom qualified.

A. F. Harper has been appointed superintendent-resident engineer at the Flat Top mines of the Sloss Sheffield Steel & Iron Co., succeeding J. W. Turner, who will be in charge of the mine operations for the State at this operation, which is worked by convicts under lease by the State.

The Newcastle Coal Co. has leased a number of its idle beehive ovens at Newcastle to the Black Creek Coal & Coke Co., which will use these ovens in coking coal from its Thermal mines now being developed a short distance from Newcastle. The Black Creek Coal & Coke Co. is building a large coal washery and installing other modern equipment for the mining and preparation of coal at its new operation and it is understood contemplates building of byproduct ovens in the future. The Newcastle Coal Co. has 374 beehive ovens, only a portion of which is required to care for the coal taken out at Newcastle mines.

Walter Moore and associates, operating the Pratt Fuel Corp., have acquired the properties of the Jagger Coal Co., in Walker County, near Nauvoo, Ala., which consists of about 2,500 acres of coal lands, carrying the Mary Lee, Jagger and Black Creek seams of coal, developments consisting of two mines and a stripping operation, the consideration involved being reported about \$350,000 cash. With this addition to the holdings controlled by the Pratt Fuel Corporation, it is stated that an annual output of 1,000,000 tons may be acquired should market conditions warrant such a production. Head offices of the Pratt Fuel Corporation are in Birmingham.

### ILLINOIS

"Educate them; make them better labor-movement men," is the idea behind a system of schooling for miners which is going into effect in Subdistrict 5 of the Illinois Mine Workers, in and around Taylorville. The

subdistrict organization has employed Tom Tippet, a well-known Middle Western writer for the Federated Press, a radical labor news service, to lay out a course in history, economics and public speaking. Classes have been organized at ten points with enrolments running up as high as 100. Tippet tours these towns conducting the classes, each of which meets once every two weeks. Later other instructors may be used. William A. Daech, subdistrict president, denies that it is a communist movement.

### INDIANA

Records of the Indiana State Board of Accounts show that Cairy Littlejohn, chief mine inspector and A. C. Daly, deputy inspector of Indiana have returned to the State Treasury amounts charged in excess of payments recorded at the hotels at which they had stayed.

Approximately 600 miners returned to work in the Indiana field this week after about three months' idleness, when three of the larger mines, the Knox mine in the Bicknell field, the Newport mine in the North Clinton field, and the Submarine mine in the Terre Haute field, resumed operations.

Co-operative mining, long a problem for the United Mine Workers of America in district No. 11, has appeared again in the Jasonville-Linton field. John Hessler, district president of Indiana says: "The co-operative mining venture at the Liberty mine, south of Jasonville, sometimes called Briar Hill, and the Keystone mine at Linton have been under investigation by the district executive board for some time." The local unions at each of those mines have been advised that unless they comply with the decision of the executive board, action will be taken against the charter of the local union."

### KENTUCKY

John Drew, a 15-year old boy employed in the plant of the Elkhorn Coal Co., near Kona Station, in Letcher County, Ky., was beheaded when caught in the blades of a large metal exhaust fan on Aug. 2.

A report from Harlem, Ky., on Aug. 5, stated that the Wallins Creek Collieries Co. had laid off 200 men and closed down because it was unable to obtain a reduction in the wage scale. It is alleged that the company signed up a four-year agreement on April 1, but later found that lower scales had been granted in agreements with other companies in the same district, which

was not in accordance with the terms of its agreement. It asked for a concession, and was refused.

It is reported from McRoberts, Ky., that, on July 26, a short circuit in Mine No. 210, Consolidation Coal Co., at McRoberts, caused a fire, which spread rapidly damaging much equipment before being brought under control. A slate fall broke electric wires and caused the fire.

A ten million dollar first mortgage is reported as filed in Madisonville in favor of the Bank of North America & Trust Co., Philadelphia, July 27, the mortgage being given by the West Kentucky Coal Co., and covering mining properties, mines and equipment, in Hopkins, Webster, Union and Crittenden County, and yards, etc., at Paducah, Louisville, Memphis, Nashville and elsewhere, including the mines recently purchased from the St. Bernard Mining Co.

Fred M. Sackett of the Sackett-Speed interests, Louisville, operating coal mines in both eastern and western Kentucky, the Byrne & Speed Coal Co., jobbers and retailers, and large cement, lime and quarry plants, on Aug. 2 received the Republican nomination for U. S. Senator by a majority of over 30,000. Sackett is popular, and a strong fighter for his state. He has served three terms as president of the board of trade, and was State Food Administrator during the war.

Frank D. Rash, of Earlington, Ky., former president of the St. Bernard Mining Co., and now vice-president of the West Kentucky Coal Co., was elected State Commander of the American Legion of Kentucky at the sixth annual convention at Bardstown, Ky., on July 26.

### OHIO

A mine of the Essex Coal Co., in the Hocking Valley, has been down for several weeks owing to a local strike which has not yet been settled. The curtailment in the company's output was approximately 5,000 tons weekly.

Bids were received by the Board of Purchase, July 30, for delivering 19,500 tons of coal to the various Columbus city institutions. W. S. Harmon, Columbus, was granted the contract for 7,000 tons of nut, pea and slack to the waterworks department on his bid of \$1.14 f.o.b. mines. On the same figure, he will furnish 3,500 tons to the garbage disposal plant. The Jay Miller Coal Co., Columbus, will deliver 9,000 tons of nut, pea and slack to the municipal light plant on a bid of \$1.25 f.o.b. mines.

Though it is still too early to fore-

cast the effect on production in the southern Ohio field of the new wage agreement signed at Logan recently, operators in that field believe it will be of considerable benefit. One of the principal advantages is the agreement on measures which will insure the production of clean coal. Another is the adoption of the eastern Ohio scale on dead work which is now on a yardage basis instead of by day labor. The price is approximately 10c. per yard.

Owing to the dullness of the coal demand both the subsidiaries of the Hysylvania Coal Co., of Columbus, viz; the Piney Fork Coal Co., and the Panhandle Collieries Co., located in No. 8 field, have been closed down.

The Kinwood Coal Co., Columbus, operating in the Jackson field on the Pomeroy division of the Hocking Valley R.R., is making extensive improvements during a temporary shutdown. An extra man exit is being constructed between the two beds which are 18 ft. apart, and both under operation. The new opening is made in case of accident. Steps will be taken soon to install an additional fan for ventilation.

Columbus operators were advised recently that the Hocking Valley R.R. had cleared up the congestion of 5,000 loaded cars of coal on the line between Columbus and Toledo, and that the temporary embargo placed last week has been lifted. Ample boats are now being provided at Toledo to handle all coal which passes over the docks. Little Ohio coal, however, is going up the lakes at this time, but much coal is passing through Columbus from ten union mines of West Virginia and Kentucky to the docks at Toledo and Sandusky. Reports from the North-west showed that coal is moving off the docks more slowly than usual at this season of the year.

## PENNSYLVANIA

The Buckeye Coal Co., a subsidiary of the Youngstown Sheet & Tube Co., is preparing to resume operations at the Nemacolin mine, in Greene County, which has been idle for a few months. The Brier Hill plant, in Fayette County, is still idle.

In front of the Lattimer offices of the North Side Coal Co., near Hazleton, is a unique war memorial to the hero dead consisting of a huge block of coal, weighing between eight and nine tons, mounted on a concrete base and with a bronze tablet on which is the inscription, "In memory of Employees of Pardee Brothers & Co., Inc., World War, 1917-1918. John W. Crooks, of Lattimer, general manager of Pardee Brothers, is the originator of the memorial.

The Lehigh Valley R.R., in addition to improving its coal-classification yards at Delano, is busy making two improvements at the Coxton yards, near Pittston, with a view to preparing for much heavier coal traffic in the future.

With the invention of a new drill, James G. Morgan, of Wilkes-Barre,

Courtesy U. S. Distributing Corp.

### Coal Pocket on Hudson River

The property of the West New York Coal Co., an auxiliary of Pattison & Bowns. This is located at Weehawken, N. J.

claims to have tripled the efficiency of a blast of powder. The bit in the drill is capable of expansion after it has penetrated into the wall, the end of the hole thus being enlarged. Several mining men have examined and seen demonstration of the drill and pronounce it a forward step in mining.

The C. M. Dodson Coal Co. has started stripping operations at Beaver Brook. It is expected that coal will be reached before the winter ties up the clay work. The company has been stripping considerable areas at Beaver Brook and a large part of the anthracite output from that section is the result of daylight mining.

The tax on undeveloped anthracite lands gradually is forcing the concentration of the industry. John H. Fetting, assistant director of the legislative reference bureau, declared the tax laws are "sadly in need of revision and codification," but emphasized the fact that any revision involves a study of more than thirty special funds of the commonwealth. He pointed out that special funds are expended under a blanket appropriation and preclude proper budgeting and control of expenditures.

Forty members of local union, No. 1036, United Mine Workers of America, of Moosic, are facing suspension from the union as the result of their refusal to pay a 25c. assessment levied by the district organization upon all of the workers in the field for the relief of idle miners.

At the staff dinner of the Peabody Coal Co., Du Bois, Pa., Charles O'Neill of Altoona, secretary of the Central Pennsylvania Coal Producers' Association, said that central Pennsylvania produced 8.5 per cent of the whole output of the United States during the first six months of this year. Pennsylvania's production has dropped from 38 per cent of the output of the United States till it is now from 25 to 30 per

cent of that production, whereas West Virginia's output has increased from 6.5 per cent to 20 per cent of the whole output of the United States. The central Pennsylvania district, he said, has decreased its production from approximately 14.5 per cent in 1890 to 8.5 per cent during the first six months of 1924.

Changes in the staff of physicians who handle compensation cases in the Wilkes-Barre and Plymouth district of the Hudson Coal Co. have just been announced. Dr. Charles L. Ashley, of Plymouth has been appointed chief surgeon in the Plymouth division. He succeeds Dr. D. H. Lake, of Kingston, resigned. In the Wilkes-Barre division, Dr. Harry Smith becomes chief surgeon. He takes the place made vacant by the death of Dr. Walter Davis. Dr. Alan Corson, of Parsons and Dr. Leo Mundy, of Wilkes-Barre, are his assistants.

The new fireproof Oak Hill breaker near Minersville was recently put in operation. The old breaker was destroyed several months back. This breaker will use the Chance method of separation.

Judge R. H. Koch gave judgment in favor of William Metcusk who claimed that he was entitled to compensation both for disability and disfigurement as a result of an explosion of gas in the mines of the Philadelphia & Reading Coal & Iron Co. Judge Koch decided that the disfigurement could not be regarded as incidental to the employment.

Five men convicted in the Somerset county court early this year for dynamiting the Baltimore & Ohio R.R. bridge at Jerome Junction and released under bail are now in the Western Penitentiary in Pittsburgh serving their sentences of five to ten years.

A new mine operation near Shamokin will be started shortly on a tract of 190 acres acquired from the J. C. Langdon estate by the Shamokin Coal Co., a new organization. The new company has the following officers: T. H. Boles, New York, the vice-president and general manager of the Lehigh Valley Coal Co., president; S. D. Dimmick, vice-president and general manager of the Glen Alden Coal Co.; C. S. Newhall, Philadelphia, vice-president of the Pennsylvania Company, Jervis Langdon, Elmira, N. Y., P. S. Gardner, New York City, mining engineer, and W. H. Johns, of Wilkes-Barre. The Shamokin company will operate a tract believed to contain 16 beds with 12,000,000 tons of recoverable coal. A first mortgage 6½ per cent bond issue has been offered to the public to raise funds for purchasing and installing new equipment.

## VIRGINIA

The new \$2,000,000 coal pier of the Virginian Ry. at Sewalls Point will be ready for operation Sept. 1, according to an announcement by C. H. Hix, vice-president of the Virginian. The new pier will be electrically operated and will have a number of innovations in coal handling. It will be self-trim-

ming, and its hoist will have a capacity of two cars at a time. In all its facilities the new pier will be one of the most modern in the world.

## WEST VIRGINIA

Bids are being asked by the Chesapeake & Ohio Ry. for building of 1,000 hopper-bottom steel railroad cars. The president, W. L. Harrahan, expects to have some of these ready to help in moving peak traffic in the fall of this year.

Chief Lambie held the third of his series of safety meetings at Beckley, Aug. 1, C. R. Stahl, assistant general manager, E. E. White Coal Co., being chosen chairman. Carl Scholz, vice-president and general manager, Raleigh-Wyoming Coal Co., presented information regarding electric cap lamps.

Officials of the A. L. Black Coal Co. and the Warner Collieries Co. in the Monongalia field will co-operate in further efforts to extinguish a mine fire which has been burning in the Black mine for several years. This fire endangers the holdings of the Warner company which has property on three sides of the Black mine. R. M. Lambie, chief of the department of mines, has recommended sealing and flooding, the stripping of coal in the rear of fire and the erection of a concrete firewall. Previous flooding failed to extinguish the fire owing to old connections with the Warner mine.

C. E. Lawall, assistant professor of mining engineering in the University of West Virginia, at Morgantown, has been designated acting head of the department with rank of associate professor. He will succeed A. C. Callen, now dean of mining at the University of Illinois. Thomas Frazer, formerly with the U. S. Bureau of Mines, and temporarily assigned to the assistant professorship of research work at the University of Illinois will replace C. E. Lawall who has been with the engineering department since 1921. Professor Lawall is a graduate of Lehigh University.

Associated with the West Virginia Coal & Coke Co. of Elkins, W. Va., in the purchase of the Main Island Creek coal mines reported in *Coal Age*, July 31, p. 160, are the Logan Mining Co., the Empire Coal Co. and the Rich Creek Coal Mining Co. It is said that the sales price for the Main Island Creek interests was about \$4,500,000 plus the inventory of the stores, commissaries and a knock-down price on other holdings.

The tippie at the Whiteman mine of the Clarksburg Big Vein Coal Co., a company operating on a non-union basis and employing 60 men, was wrecked Aug. 7 by two explosions. Timbers were hurled more than 300 ft. and nearby homes were shaken. This is the third tippie destroyed in the last few weeks at the non-union mines of Harrison County.

The Crystal Block Coal & Coke Co., Welch, W. Va., has voted to issue \$200,-

000 of preferred stock, to complete the development of a new operation at Stirrat in the Logan field on Main Island Creek, making total capital \$700,000. It will be one of the best operations in southern West Virginia and well equipped with preparation machinery. The company has about 1,300 acres and has already completed work on 34 houses and driven its opening about 600 ft. The company expects to ship coal in small quantity in about two weeks.

## CANADA

It having been alleged by an alderman of the City of Hamilton, Ont., that the municipal coal department conducted by that city this year was incurring heavy loss, the City Clerk has made a statement that up to June 1 a surplus of \$2,300 has been earned.

Archibald McCool, general manager of the British Empire Steel Corporation's operations on the mainland of Nova Scotia, has resigned his position.

The British Empire Steel Corporation has announced a decrease in salaries ranging from 10 to 25 per cent, for executives of the company. Affected are superintendents, engineers, foremen, office managers, purchasing agents, office clerks and shipping department employees, etc. Some of the principal officers have resigned in protest against the cuts. Because of the shutdown of the steel plant at Sydney for three months, a substantial decrease is expected for the next three months in the coal mined in the Cape Breton district.

The Allen mine which was the scene of a disaster on Cape Breton island some months ago, has been closed, apparently for an indefinite period. No repairs are being made. The production of coal by the British Empire Steel Corporation, is about sixty per cent normal. This is attributed to the depression in business. At nearly all the mines are heavy stocks of coal awaiting sales.

## New Companies

Articles of incorporation have been filed in Birmingham by the **Continental Coal Co.**, with a capital stock of \$4,800, all paid in. The company was formed by T. S. Abernathy, G. G. Tait and J. M. Donaldson.

**The Jagger Coal Co.**, Nauvoo, Ala., has filed notice decreasing its capital stock from \$198,000 to \$20,000.

**The Castlegate Fuel Co.** of Salt Lake City has filed incorporation articles. Chas. M. Goddard is president. The capital stock is listed at \$25,000.

**The Mutual Development Co.**, of Pikeville, Ky., for development of coal properties, was recently chartered with a capital of \$75,000, by J. J. Moore, L. H. Moore and Edward Hellier.

**The Northern Alabama Coal Co.**, Jasper, Ala., has filed papers for incorporation permitting it to enter the coal-mining business. The incorporators are Walter Moore, C. P. Moore and Bird Tichenor. The capital stock is \$247,500, only \$2,500 of which is paid in.

**The Peerless Elkhorn Coal Co.**, of Columbus, Ohio, has been incorporated with an authorized capital of \$150,000 to mine and sell coal in the Elkhorn field of Kentucky. Incorporators are F. G. Hatton, E. Hauck, Ralph G. Martin, Ralph E. Marburger and

Ralph E. Weaver. The promoters are not yet ready to announce the details of the development.

**The Youngstone Coal Co.** has just been launched with a view to engaging in the production of coal in northern West Virginia. This company is capitalized at \$100,000. The headquarters of the concern are at Morgantown. Having an active part in forming the new company were: Erwin B. Stone, W. D. Stone, E. B. Stone, Sr., F. A. Stone, and Ethel Stone all of Morgantown.

Huntington people have organized the **Alma Pond Creek Coal Co.**, with a view to developing an acreage of coal in the Thacker field near Sprigg, W. Va. The new concern is capitalized at \$150,000. The office of the company will be at Sprigg. Principally interested in the new concern are H. L. Rucker, R. C. Pforr, P. P. Gibson, D. G. Hughes and M. F. Breslin, all of Huntington, W. Va.

## Industrial Notes

**The Maine Electric Co.**, manufacturer and distributor of steam and electric hoists and derricks, coal-handling plants and marine auxiliary machinery, has opened a Philadelphia office at 814 Walnut Street, Philadelphia, Pa. The new office will be in charge of F. V. Wetherill.

**J. F. Buhr** has opened an office in the Blodgett Engineering & Tool Co. Bldg., at 14th and Daizelle Sts., Detroit, Mich. The J. F. Buhr Machine Tool Co. will act as sales representatives for the Blodgett engineering and tool products.

H. M. Richards was recently appointed district manager in charge of the Cleveland district office of the **American Rolling Mill Co.** For a number of years he was located at the home offices of the company, and in recent years has been attached to the Pittsburgh district office. J. T. Hagan, of Cleveland, is associated with Mr. Richards in his new work, and the office is now at 1408 B. F. Keith Building.

The **Chicaco Pneumatic Tool Co.** announces the transfer of Ross Watson, formerly district manager of the Cleveland office of this company to the district managership of the Minneapolis branch to succeed D. M. Westbrook, now general manager of the Canadian Pneumatic Tool Co. Other recent changes include the transfer of L. J. Westenhover, from the Pittsburgh Office to Cleveland as District manager of that branch and E. C. Stroup, compressor engineer in the Boston territory, has been moved to the Pittsburgh District.

**Peter G. Rimmer**, for many years in charge of the Wilkes-Barre office of the Ridgway Dynamo Co., has resigned the position which he has held for the last two years with the Scranton Electric Construction Co., and on July 1 again took charge of the Ridgway office at Wilkes-Barre. E. W. Quiggle, who has been in charge of the Wilkes-Barre office during Mr. Rimmer's absence, is returning to the factory office at Ridgway, Pa.

The Buffalo office of the **Cutler-Hammer Mfg. Co.**, located in the Ellicott Square Bldg., formerly a part of the Eastern district, has been made part of the Central district, of which A. G. Pierce is general district manager, with headquarters at Pittsburgh. The Central district includes the territories covered by the Buffalo, Pittsburgh, Cleveland and Cincinnati offices. B. A. Hansen is manager of the Buffalo office.

## Association Activities

The annual banquet of the **Virginia Coal Operators' Association** at Norton was attended by about 150 operators and guests. Horace Williamson, of Cincinnati, presided. Harry L. Gandy, of Washington, executive secretary of the National Coal Association, the principal speaker, urged open frankness in meeting and dealing with the problems of the coal industry. He asserted that the fourth amendment to the federal constitution guaranteed the right to peaceful possession of private property, free from aimless fishing and probing, assuring his hearers that the National Association had justified its existence in challenging through the Maynard case the federal right of indiscriminate interference with private industry, if by nothing else that it has done.

## Traffic News

### Make More Protests Against Northwest Rate Revision

Almost every day some new party enters the lists against the rate revision on Illinois rail coal for the Northwest which the Interstate Commerce Commission has ordered for Sept. 10. The Wisconsin Traffic Bureau of Chicago, representing a large group of paper interests, has filed the latest petition with the Commission for a reopening of the case. Other recent ones were filed by the Waldorf Paper Products Co., of St. Paul, Minn., the Hydraulic Press Brick Co., of Minneapolis and the Twin City Coal Exchange. Up to August 1 the Commission had stood pat, however, so carriers are preparing to advertise the new tariffs.

### Indiana Rate Is Upheld

The carriers of Indiana failed to get the federal court to uphold them in their desire to maintain the present Indiana intrastate rates on coal. So the new low tariffs ordered for Aug. 1 by the Indiana public service commission took effect that day. Judge Samuel Alschuler, one of the three federal judges who sat *en banc* on the railroads' appeal for an injunction against the state commission, charged the roads with "panhandling" their case about from court to court in an effort to find one that would favor them. "You are bound by the decisions of the Indiana Court," he said. The state courts had already declined to interfere in the case. The roads are now petitioning the I.C.C. to interfere.

Fifty manufacturers in the Rock Island-Moline (Ill.) region are asking the State Commerce Commission for reductions in intrastate rates on coal to those cities. They point out that many other regions have recently been favored with rate cuts.

The application of the City of Watertown, S. D., for a suspension of the increased freight rates on coal to Watertown and other South Dakota points, in connection with the new rates on steam coal, has been refused by the Interstate Commerce Commission.

## Recent Patents

**Mining Machine.** Edmund C. Morgan, Chicago, Ill.; Olive E. Morgan, executrix of Edmund C. Morgan, deceased; 1,480,003. Jan. 8, 1924. Filed Jan. 5, 1916; serial No. 70,341.

**Spiral Lowering Chute.** Frank Pardee and Frank Pardee, Jr., Hazleton, Pa.; 1,480,105. Jan. 8, 1924. Filed April 28, 1922; serial No. 557,063.

**Scraper.** Leslie P. Green, Chicago, Ill.; 1,480,389. Jan. 8, 1924. Filed June 24, 1921; serial No. 479,991.

**Crossover Mine Switch.** Robert T. Bagby, Birmingham, Ala., assignor of one-half to E. M. Kilby, Birmingham, Ala.; 1,480,739. Jan. 15, 1924. Filed June 9, 1923; serial No. 644,343.

**Electric Accumulator or Battery for Miners' Safety Electric Lamps.** Richard Koch, Pittsburgh, Pa.; 1,480,764. Jan. 15, 1924. Filed Feb. 9, 1923; serial No. 617,980.

**Mine-Door Operating Apparatus.** Harry Frank and John Lewis, Fork Ridge, Tenn.; 1,481,128. Jan. 15, 1924. Filed April 13, 1922; serial No. 552,119.

## Obituary

**Grant Hubley**, vice-president and director, Greensburg-Connelville Coal & Coke Co., died July 20 of injuries received in an automobile wreck June 30. He was vice-president and general manager of the Oil Well Supply Co., of Pittsburgh.

**George W. Atkinson** of Louisa, Ky., died late in July at a Huntington, W. Va. hospital to which Mr. Atkinson had been removed after a few days' illness at his own home. He had, however, been in poor health for some time. Mr. Atkinson was 56 years of age.

For many years he had been identified with the coal industry of southern West Virginia, being originally identified with the Flat Top Coal Co., now the Pocahontas Coal & Coke Co. Later he was associated with the Guyan Coal Land Co. in Wayne county, a subsidiary of the Flat Top Coal Co. Mr. Atkinson organized the William Light and Power Co. and also the Logan Light and Power Co. He was at the time of his death, owner of the water works at Louisa.

Mr. Atkinson was a graduate in civil and mining engineering of the Virginia Polytechnic Institute of Blacksburg, Va., and a native of Montgomery County, Va.

## Coming Meetings

**New York State Coal Merchants Association, Inc.**, 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

**American Chemical Society.** Fall convention Sept. 8-11, 1924, at Ithaca, N. Y. Secretary Gas and Fuel Section, O. O. Malleis, the Koppers Co., Pittsburgh, Pa.

**Oklahoma Coal Operators' Association.** Annual meeting Sept. 11, 1924, McAlester, Okla. Secretary, A. C. Casey, McAlester, Okla.

**Association of Iron and Steel Electrical Engineers.** Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### For Spraying Surfaces

Many walls should be sprayed to make them airtight. No stopping, no furnace wall is tight if made out of brick and not coated with some kind of plastic material. The equipment illustrated is designed to spray plastic material on boiler baffle walls but it has other uses. It may be used to patch roofs and walls of furnaces of all kinds. It can be operated by air or steam pressure; the movable bottom lifting under pressure and expelling the liquid.

By means of a pipe leading direct to the hose any material clogging the hose or nozzle can be blown out by air or steam whichever furnishes the power for the operation of the machine. The long nozzle places the material in the most inaccessible places in either hot or cold furnaces. With this type

Sprayer for Plastic Material

The cylinder rapidly is filled with the plastic mixture through the cover at its top. This is replaced and screwed down. Air or steam is admitted below the piston and the liquid above it is expelled under pressure into the hose and nozzle.

of equipment labor is saved and the time lost in shutting down for repairs. The equipment is made by the Co-operative Utilities Co., 1014-1015 Harrison Building, Philadelphia, Pa.

### Man-Cooling Shop Fan

Hot work is a trial in warm weather. Many a blacksmith or foundry man would do better work if kept cool by a fan. Any kind of shop man will be better contented and more active if given a breath of fresh air in warm, humid weather. A man-cooler has been developed by the Buffalo Forge Co., of Buffalo, N. Y. This unit is made in two sizes, the larger having a 36-in. diameter fan wheel, and the smaller a 30-in. wheel. The entire fan is of heavy construction to insure against vibration. The screen inclosing the fan wheel is extra heavy, and the rim itself is made of 2½ x 2½ in. angle. The unit, however, can be moved easily.

This fan has only three essential parts—the fan wheel, a direct-connected motor, and a pedestal. The wheel is

### Fan Cools Shop in Hot Weather

Blades revolve at speed of 900 r.p.m. Screen is heavy with strong rim. Made for the rough usage likely to be sustained by a shop fan.

composed of ten blades so designed that the air is delivered in a concentrated stream. This factor of air delivery gives the best cooling efficiencies at the lowest expenditure of power. A direct-connected motor placed directly back of the fan wheel supplies the motive power. The 36-in. man-cooler fan is supplied with a 5-hp. motor, and the smaller fan is equipped with a 3-hp. unit. The speed for fans is 900 r.p.m. The pedestal is a heavy casting; four bosses are provided in the base for foundation bolts in case the fan is kept in a permanent location.

### Mine Hoist Is Provided with Electro-Pneumatic Control

An unusual and interesting type of control for a large mine hoist will be put in operation in the early part of this coming autumn by the Lehigh Coal & Navigation Co., Lansford, Pa., at its No. 4 shaft. The installation will consist of a 1,200-hp. 300/293 r.p.m., 2,200-volt, three-phase, 25-cycle, wound-rotor induction motor, which will be controlled by electro-pneumatic-unit-switch type of contactors. Each contactor is closed by air pressure against a powerful spring, the action of which produces positive closing and a quick break when opening.

The primary reversing contactors will consist of three 2-pole elements, electrically and mechanically interlocked and mounted on a steel supporting frame, totally inclosed. The inclosing covers will be provided with a specially designed muffler to deaden the noise, characteristic of all high-voltage air-break contactors. The secondary accelerating contactors will consist of twenty-four unit switches mounted on three separate steel frames, giving nine accelerating points. These contactors will not be enclosed, as the only noise is that accompanying the escaping air when the contactors open. Because of the noiseless operation of the accelerating contactors and their separation into three frames they can be mounted near the motor with the grid resistors and thus utilize waste space which will result in a material saving in the cost of installation.

The action of the electro-pneumatic contactors is governed by the manipulation of a small master controller, the contacts of which control an electrically operated air valve on each unit switch. Automatic acceleration is obtained by current-limit accelerating relays and interlocks so that each switch will operate in the proper sequence without excessively high currents.

Every safety feature is provided for the successful operation of the complete equipment. The failure of the alternating-current power, the air pressure or the control circuit, or the occurrence of an overtravel will immediately open all main switches and apply the hoist brakes. This control is being furnished by the Westinghouse Electric and Manufacturing Co.

### Machine-Tool Controllers for Direct-Current

Magnetic machine-tool controllers recently have been placed on the market, employing the counter-electromotive force method of acceleration. These controllers are applicable to both reversing and non-reversing, constant

### Reversing Type Controller

Acceleration is governed by the counter-electromotive force generated in the motor.

and adjustable speed drives requiring normal starting conditions. They have been developed primarily for application to direct-current motors in sizes ranging up to and including 15 hp.

The controller provides two accelerating points; the starting resistor is automatically short-circuited in one step upon proper acceleration of the motor. This is accomplished by an accelerating contactor the closing of which is governed by the counter-electromotive force of the motor.

These controllers are made by the General Electric Co. Coincident with the adoption of the new type of starter for its smaller motors, a complete redesign has been made of its larger types of magnetic machine tool and general purpose controllers.

### Low Switch Stand Has Throw Parallel to Track

A longitudinal-throw switch stand of low height and simple construction recently has been patented by Louis A. Green and will shortly be placed on the market by the L. A. Green Railway Equipment Co., of Pittsburgh, Pa. In the design of this stand the object sought was the provision of a simple, durable device of small first cost, particularly adapted to use in the restricted passages of mines, tunnels and the like.

In detail this stand consists of four chief parts, namely: (1) A stand or support, (2) a hand lever pivoted at one of its sides, (3) a link or lever connecting this hand lever with (4) a vertical shaft, provided at its lower end with a crank that engages a link or connecting rod joining it to the bridle bar of the switch.

As may be seen in the accompanying illustration the vertical shaft which is pivoted to the stand at its upper end is slotted. Through this slot works the lever which joins this shaft to the hand lever, which latter is curved slightly inward at its lower end. The arrangement is such that in either the open or closed position of the switch the hand lever, which is usually weighted, lies parallel with the ground.

It is usually conceded that a longitudinal or parallel-throw switch is safer than one having a transverse-throw, for in working the lever the switchman is not compelled to reach near the track to either raise or depress the lever. He is thus at a safe distance from the locomotive or trip at all times, and is not liable to pitch forward over the track. Furthermore, a low stand such as this one does not offer an appreciable obstacle to passage through a heading in which a trip is standing.

### Switch of Simple Construction And Minimum Height

The simplicity of this switchstand is apparent at once — and simplicity means both reliability and low first cost.

## Give and Take

WE HAVE ALL the impatience of Eugene McAuliffe with the persons who sit back in their seats and listen to the discussion and who take and never give. We have as much respect for them as we have for those numerous people who are frequently guests at other people's tables and never have guests at their own. If they have nothing of their own to give, of course they are excused, but if they have much and pretend they have none or withhold when they are anxious to receive, theirs is a mean and sordid part indeed. American?—not at all. They live in a little land of their own, making forays on such of their neighbors as they see have, or may have, something they want.

## Troubles from New Financing

SOME OF THE large projects being put into operation by money obtained from financing in New York and elsewhere, the money not coming from the industry but from bankers, is occasioning difficulties between capital and labor, for the employees not knowing where the money comes from believe that in some mysterious way it is derived from the profits of coal production. That assumed, they believe the present unprofitableness of operation is subject to grave doubt.

Instead, it is the fear that profit will be lacking and losses will be more severe than before, that is making mine owners expend borrowed money for purposes of efficient operation. Operators are obliged to go outside to get the sinews of war to wage a successful fight against competing operators. Especially is this true in the union fields. The mine workers are ill-advised to interfere with operation, because only by large expenditures at the mining plants at which they work can they hope to retain their employment. A few strikes may make the operators less willing to attempt what is so essential for the welfare of both the men and the company.

## Coal by Pipe

PROFESSOR GEORGE GUESS, of the University of Toronto, told the British Association for the Advancement of Science that eventually we would circulate powdered coal through pipes to domestic furnaces. He declared that better temperature control and greater economy would result.

The idea is not by any means wild. Gas is not a sufficiently dense fuel for us to get satisfactory results from its piping, even under high pressure. Coal could be circulated as dust under a lower pressure than has been proposed for gas and even though it is mixed with air would deliver many more thermal units than an equal volume of gas. Of course, mixtures of coal dust and air in a pipe might be dangerous when a flame is at the burner, but so far no danger has been experi-

enced, probably owing to the small area of the orifice and the hazard may be as remote as the passing of flame back through gas pipes, though the presence of air in the case of pulverized coal justifies a little caution in adopting such a plan, which might introduce danger if a pipe were broken.

If Professor Guess' suggestion is any more than a mere day dream it would seem advisable that the operators test its possibilities. What a wonderful opportunity for the proposed Coal Institute!

## No Time to Idle

WHEN MINES are idle is a good time to clean up fallen airways and mend or replace leaking brattices. Air is getting to be an expensive item in mine costs. It does not pay to drive or draw it through airways choked with fallen rock or filled with heaved clay. It is extravagant to waste it at leaky stoppings. When the mines are idle, the track is clear and empty cars are plentiful is a good time to make these improvements under the vigilant inspection of the mine foremen. It is daywork and so needs close supervision under and above ground.

In such times as these it is well to examine costs and see what it will save to make certain improvements now or later. Too many mines are ruined by robbing airways and headings that might have been kept intact had a thought been given to their possible use as intake or return airways.

This is the time for planning, even if no money is granted for improvements. If the change cannot be made now, the work may be estimated as to quantities and cost so that when opportunity does come a proper statement of investment, advantages and savings may be promptly presented without the delay of a survey and a study.

## Going Dry

WE MUCH regret that the report of the Safety Committee of the Rocky Mountain Coal Mining Institute spoke a word for humidification and sprinkling. We expect the West to lead in rock dust, first because it has a plentitude of that commodity and secondly because it has a shortage of water. Winton, Wyo., that has led the West in rock dusting may be shorter of water than other mining villages but surely many others are not far behind.

Why then should the West cling to humidification, except at the working faces and for laying the dust on cars, loaded and unloaded? As for sprinkling, it is hopeless in a dry climate. We believe in immersion rather than in sprinkling, but where is the water that will keep a Utah or a Wyoming mine properly immersed?

Because, however, there are some who still may want to use sprinkler cars, despite their undoubted disad-

vantages and because we shall probably continue to use water in rooms as a way of attacking explosions a little nearer the source than is possible where headings only are sprinkled, one of these devices is portrayed this week in "Problems of Underground Management." Sprinkling pipes carried to the face have the advantage that they can be used at any time. The sprinkler car has much to commend it, especially the breadth, length and elevation of its application of water and the fact that its use is not likely to be slighted by the man who should do the sprinkling, but it does not have the merit, except when shotfirers are employed, of performing its work near the time of maximum peril, which is when the place is being operated and shots are being fired. If the cutter-bars are to be sprinkled, the pipes will be on hand for a general sprinkling of the face, and also of the room gob and in that event the sprinkler car will have a difficult time justifying its existence. Times change rapidly. A few months ago everyone was looking for a sprinkler car, and now the nation has gone dry.

### Let Politicians Beware

POLITICAL activity has made Great Britain examine her industries with care. They have been found wanting, of course. They do not work steadily. They do not give the workman all that he needs. Hence the politicians have been able to indict industry quite satisfactorily.

Now the politicians are asked to reform industry and if they cannot reform it, to take it over and operate the factories, the mines and the mills better than the corporations are doing. This is a hard problem for politicians to solve. They are proving even less successful than the industrialists and the result is the people are ill satisfied. The argument, "If you don't like the way it is done, do it yourself" is disconcerting if the man who is asked to do it doesn't know how. The politicians will try anything once. But they will find they are face to face with a problem they cannot solve.

The working men are not satisfied with the solution proposed in the "Coal and Power" report of the Liberal party, of which we published a happily worded description by George Otis Smith last week. It does not rest satisfied with reasonable royalties, it wants no royalties whatever. Both profits and royalties are taboo as also the closing down by a uniform wage scale of inefficient mines. It must be remembered that workmen will have to move or be idle who have been working at naturally difficult operations if such mines are put out of business. So the report, radical as it is, will satisfy no one. The politicians have stirred up a ghost that they cannot down.

Though it is a fundamental tenet that government is for the people and not the people for the government yet at the same time that doctrine has so often made a dependent and weakling democracy and the opposing tenet strong and progressive nations, that it would seem better to beware of accepting in too full a sense the conviction that the purpose of government is to coddle and mother the individual, but rather to keep steadily in the forefront the idea, ridiculous as it may seem, that the purpose of government is to establish an ideal to which the individual can render a perpetual service.

### The Worst Industry

MANY a perfectly good fact has been ruined by a carelessly appended superlative, and perhaps it would not be well to suggest that there is any worst industry among the many that might run close for that unenviable distinction. Still, if we had to award the booby prize it would probably go to the constructors of houses, water-works, roads and railroads rather than to the coal men on whom this discredit is usually pinned.

No industry works more irregularly than that of construction as we have often pointed out. None houses its men in more insanitary, overcrowded and impermanent hovels when housing has to be provided. Men are herded into box cars, lodged in adobe huts or thrust into long bunk shanties with little or no consideration as to health, comfort or morals. Justice compels us to admit that these conditions had some excuse and that recent years have shown much improvement in the building of construction camps.

One might add, if one had statistics to ascertain it, that none has a higher record for accident. Few workmen have been guilty of more violence than the iron workers. Few have had more stringent rules against large output and efficiency than the construction unions, and this industry is almost the only one that has jurisdictional strikes. The construction industry, if not the worst, is so near that goal that you will not need to travel further when it is reached.

Says a Committee of the President's Conference on Unemployment, "Building trades' workers in the average American city, it appears from information gathered in our survey, are employed at their trade less than three-fourths of their time. In the average year these men must be paid enough that they can support themselves and their families for twelve months on wages received for seven to ten months' work.

"For most contractors the overhead costs for maintaining their offices and staff during the whole period of twelve months must be charged against the jobs carried on actively during only seven or eight of those months. Supply dealers must maintain establishments big enough to handle a large quantity of work during four or five months. These establishments are practically idle during at least three months and are operating at only a fraction of their capacity during the rest of the year." And so on for building material manufacturers and architects. All this sounds like the indictments that have been and are being passed on the coal men. There is the old familiar ring. The judge's verdict is the same but another culprit stands disconcertedly at the dock.

As for combinations in restraint of trade, the resemblance is not so close. The coal operators have been charged with violations of the Sherman Act but the allegation has never been proved. The material trades and the constructors, both only in part, have been accused, but in their instance the charge has been sustained.

We are not ready to condemn those faults which are almost unavoidable in the construction industry, but we cannot but be reassured by knowing that unemployment, excessive pay to counterbalance short time, bad housing, undue accident rates, violence in strikes, restricted output, insufficient ability to fill crying needs, excessive prices and costs with combinations in restraint of trade also are alleged of an industry that so far has escaped general condemnation. We would like to know why?

General View, Winterslag

## Campine Region—A Coal Field with No Completed Shaft Less Than Two Thousand Feet Deep

Coal Discovered in 1901—Apparently Portion of Field Extending from England to Germany—  
Coal of Excellent Quality Especially for Metallurgical Fuel—Longwall  
Mining and Rope Haulage Adopted

BY D. ADAM\*  
London, England

EARLY IN THE nineteenth century geologists speculated on the possibility of finding, under the Secondary and Tertiary formations of Northern Belgium, a concealed coal basin linking the Westphalian field with that of the English Midlands. It was not, however, until 1876 that the theory took definite shape in the writings of Guillaume Lambert, then professor of geology in the University of Louvain. The theory was still more strongly advocated by his pupil André Dumont, son of the celebrated Belgian geologist. In 1901 Dumont obtained verification of his beliefs from a borehole that he and his associates in a prospecting company put down near the little village of Asch.

News of the discovery of coal below the moors and sand dunes of the Campine created a profound sensation in Belgium, and during the following three years over sixty boreholes were sunk by various prospecting parties. Although in many cases too hastily drilled to give exact information about the overburden, these boreholes served to indicate approximately the northern and southern boundaries of the basin and to confirm the hopes raised by the first discovery. But they showed also that there existed a formidable obstacle to commercial exploitation in the overlying strata which consist in large part of running sand and clay, extending to depths of 500 to 600 m. (1,640 to 1,968 ft.). It became evident that shaft sinking would require a far greater capital outlay than had been usual in the southern field and that mining operations would have

to be conducted on a big scale in order to provide for the redemption of this investment.

Fortunately the Campine basin proved to be rich in coal of a quality that hitherto had been lacking in Belgium. The gas and coking fuels of the upper measures had not been denuded as in the regions of Liège, Charleroi and Mons, and in themselves were sufficient to attract the capital necessary for their exploitation. Much of this capital came from iron and steel manufacturers in France and Belgium who were interested; not only in the profit derivable from mining operations, but in opening up a source of coking coal that would make them independent of foreign supplies.

### SEVEN COAL COMPANIES START OPERATIONS

In 1906 eight concessions were granted, this number being increased later to nine. Today seven operating companies are working on these concessions. The most advanced of these from the point of view of exploitation is the Charbonnages de Winterslag with an output of 2,500 to 3,000 metric tons per day (2,755 to 3,306 net tons) and equipped to handle an output of 4,000 metric tons (4,408 net tons) when sufficient faces have been developed. Its subscribed capital consists of 12,000 shares (of no par value), 26 million francs (now \$1,310,000) in 4½ per cent bonds and 34 million francs (now \$1,715,300) in 6½ per cent bonds. On the balance sheet presented in June last the concession and plant were valued at 75 million francs (now \$3,783,750). For the financial year ended March 31, 1924, the shareholders received a dividend of 300 francs (now \$15.04) per share, the first since exploitation proper began in October, 1917.

Adjoining Winterslag on the north is the concession

\*University of Glasgow.

NOTE—At the Winterslag colliery shown in the headpiece, cars are moved from the shaft at the right to the screening and washing plant on the left over an elevated trestle by means of an endless chain. The mine offices, bathhouse, lamproom, etc., may be seen on the right, some of the mine dwellings appearing in the foreground.

of Charbonnages Liegeois and on the east that of Charbonnages André Dumont. Both these were practically at a standstill during the four years of the German occupation and are today only in the initial stages of exploitation. The former company with a capital of 80 million francs (now \$4,036,000) has one shaft sunk to a depth of 860 m. (2,822 ft.) with main galleries being driven to open three beds. In the second shaft, sinking was delayed by an influx of water at the 340-m. (1,115-ft.) level but has now been resumed. The two shafts of the Charbonnages André Dumont have been sunk to depths of 710 and 700 m. (2,329 and 2,297 ft.) respectively and already, with temporary hoisting equipment, a small output is being obtained from the development entries.

At the eastern end of the field, with one boundary on the Dutch frontier, are the concessions Guillaume Lambert and Sainte-Barbe, belonging to the Charbonnages Limbourg-Meuse. This company with a capital of 75 million francs (now \$3,783,750) has already reached the production stage, though still far short of its calculated normal output. At the present time exploitation is concentrated chiefly in three beds at depths ranging between 600 and 700 m. (1,969 and 2,297 ft.). At the opposite end of the field is the concession of the Charbonnages de Beeringen (capital 75 million francs, now \$3,783,750) which, after Winter-slag, is the most advanced of the Campine collieries. For the first quarter of 1924 it had an output of 64,000 metric tons (70,528 net tons).

The sixth operating company, Charbonnages de Helchteren et Zolder, with concessions adjoining Beeringen on the west, is still engaged in shaft sinking. One shaft entered the coal measures in June, 1923, at a depth of 700 m. (2,297 ft.) and the other is expected to reach the coal measures in September or October of this year. Another operating company, La Société de Houthaelen, was formed at Brussels in July, 1923, with a capital of 35 million francs (now \$1,765,750). It is at present only at the stage of prospecting its concession.

Though much remains obscure in the geology of the Campine field, sufficient development has been performed to indicate its general structure and its relationship to the great Anglo-German basin. The known

Fig. 1—Location of the Campine Field

This field is apparently a portion of the great coal basin that stretches from Ireland to Germany or possibly even into Russia. Although coal was long believed to exist in the Campine it was not until 1901 that a borehole proved its location.

Fig. 2—Detail of the Concessions Granted

Eight mining areas or concessions have been granted and three reserve areas are held by the state. In some concessions production has started, but the others are as yet in little more than the prospecting stage.

facts hitherto scattered through many different publications have been summarized recently by Professor Stanier\* who, as consultant geologist, has taken an important part in the prospecting work.

It is now established that the Campine basin is a portion of the long field starting in Westphalia and traversing the province of Limburg in Holland, the Campine, Province of Antwerp, Zeeland, the North Sea and the Midlands of England. It was apparently protected from denudation and from the folding which has greatly disturbed the Liège-Charleroi-Mons basin by the vast Siluro-Cambrian anticline of South Wales and Brabant. It has been affected, however, by a complicated system of faults. One set of these appears to dislocate only the coal measures.

#### CROSS FAULTS DIVIDE FIELD IN COMPARTMENTS

The general direction of this first set of faults is north-west to south-east, but there are also cross faults at right angles with it which divide the coal measures into a series of box-like compartments. The second set of faults limits the basin on the north and probably also on the south. The northern faults affect the strata from the coal measures to the Quaternary gravel and have been compared by Professor Stanier to a gigantic staircase, displacing the coal measures to a depth of more than 2,000 m. (6,562 ft.) below the Tertiary rocks of the Fosse de Ruremonde, a depression well known to Dutch geologists who have approached it from the other side.

Their position along the southern boundary of the field remains obscure, for no boreholes have been continued beyond the carboniferous limestone at the base of the coal measures. It appears probable, however, that the Campine basin is completely detached from the Liège basin by the Siluro-Cambrian anticline of Brabant. On the east there is connection with the coal measures of Limburg in Holland and on the west with the unexplored basin of the province of Antwerp, which, for the time being, is retained as a government reserve.

The Campine coal measures belong to the Westphalian system and it is to the upper portion, in a band known as the Genck series, that development is at present confined. The prevailing dip is about 5 deg. in a north-

\*"Résumé de Nos Connaissances sur la Géologie de la Campine" Annales des Mines de Belgique, 1924 t.XXV Ire. Livraison p. 163.

early direction, with the line of strike forming a curve. The faulting, however, to which reference already has been made, causes many local variations in dip and strike. The number and thickness of the beds encountered in the different shafts and boreholes also vary considerably. Some typical sections are shown in Fig. 3.

A calculation made by Professor Denoël of Liège University gives the following figures for the reserves in the basin. These are based on the assumption that extraction can be carried to a depth of 1,500 m. or 4,921 ft.

	Millions of Cubic Meters
Gas coal .....	3,600
Coking coal .....	2,900
Semi-bituminous coal .....	400
Total .....	6,900

Assuming that the density of this coal is 1.25 and that a possible extraction of 75 per cent can be attained,

lining of the shaft with cast-iron tubing down to the top of the coal measures. In the earlier shafts the ground was frozen only to the Tertiary shales at a depth of about 340 m. (1,115 ft.), the intention being to use cement injections should further water-bearing beds be met. This plan, however, left out of account the Hervian Sand which swallowed cement, without any diminution of its flow or pressure.

In the end, freezing had to be resumed at the lower level and, as this is a difficult and costly operation, the later shafts were frozen all the way to the coal measures. The only shafts which escaped the Hervian Sand were those at Winterslag, where, by some fortunate chance, only the upper portion of this band was met. It was this good fortune that allowed Winterslag to get so far ahead of its neighbors, though they began sinking at the same time.

Before the sinking of these Campine shafts, the greatest depth to which freezing of the strata had been carried was 300 m. (984 ft.). To advance at one step

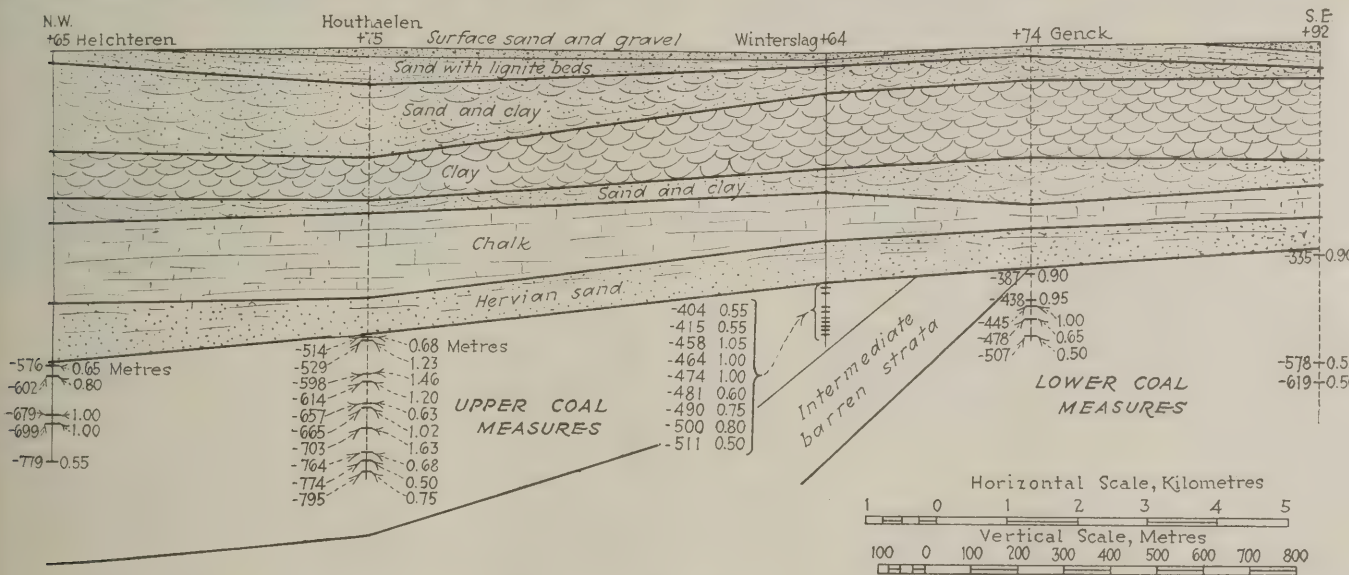

Fig. 3—Cross-Section of the Coal Measures Along Line XY of Fig. 2

Presence of the Hervian Sand which carries much water under high pressure makes shaft sinking difficult. This sand literally swallows cement without any appreciable effect. Consequently it was necessary to freeze the measures surrounding the shafts. Although this process is slow it has proved highly satisfactory, and shafts thus sunk when lined with cast iron are practically dry

there is a reserve on the basis of Professor Deonël's figures of more than 6,000 million metric tons (6,612 million net tons) in this field. If mining were limited to a depth of 1,000 m. (3,281 ft.) the quantity would be about 4,000 million metric tons or 4,408 million net tons.

All formations subsequent to the Carboniferous are represented in the strata overlying the coal measures of the Campine, though it is only to the north in the Fosse de Ruremonde that the complete sequence is found. At the top of the coal measures now being worked there appears to be an unconformable junction with an upper band of the Cretaceous, known locally as the Hervian Sand. This is of evil repute in the Campine, for, though in its upper layers it consists of a sandy chalk or marl, at the base it becomes nearly pure sand, heavily watered and offering a formidable obstacle to sinking operations. Above this Hervian Sand there is an exceptionally complete sequence of Tertiary strata to the Quaternary gravel and sand of the surface.

In all the shafts sunk in the Campine it has been necessary to use the freezing process, followed by the

to a depth of 600 m. (1,968 ft.) was a great achievement in engineering for which credit must be given to the late Louis Sauvestre, who had charge of the sinking at Beeringan and to the Foraky Boring & Shaft Sinking Co., Brussels, which drove the first three shafts to reach the coal measures and has since, either alone or in collaboration with other contractors, had a hand in sinking most of the Campine shafts.

Thanks to the experience thus gained, the sinking of shafts by the freezing process to depths of 600 to 700 m. (1,968 to 2,297 ft.) now can be undertaken with the same certainty and security as sinking by ordinary methods through dry rock strata. The work is naturally slower and more costly but results in as perfect a shaft as any that can be sunk in the most favorable ground. Notwithstanding the reservoir of high-pressure water encircling the shaft, the inflow, after the tubing is placed and the ice wall thawed, is insignificant.

So dry indeed are these shafts that in subsequent sinking through the coal-bearing strata the men employed frequently discard their customary garb of oil-

skins. In the producing mines the water inflow is small (at Winterslag 8.5 cu.m. or 2,245 gal. per day) and the workings are dry. The shafts are  $5\frac{1}{2}$  to 6 m. (18 ft. to 19 ft. 8 in.) in diameter and are divided into four winding compartments.

The resemblance of the Campine coal field to that of the English Midlands, with its flat regular beds, has led to development on the same general plan as that followed in the longwall workings of the English collieries. This plan, however, has been modified by ideas and habits transplanted from the Liège-Charleroi-Mons coal field. At Winterslag the bed is entered from the shafts by two parallel galleries. From these, two main entries are driven as nearly as possible to the rise, but at a gradient not exceeding 3 deg. Between them is carried a longwall face 100 m. (328 ft.) in length. One of the entries serves as an air intake and main haulage road and the other as a return airway.

#### OSCILLATING CONVEYORS USED AT THE FACE

From these passages lateral entries are projected on a straight bearing following approximately the level course or strike of the bed and between them are carried longwall faces 80 to 100 m. (262 to 328 ft.) long. Fig. 4 illustrates the general scheme of the workings. In practice it is not possible to keep strictly to this geometrical plan, as faults and other disturbances interfere. The aim, however, is to block out the coal in these 100-m. panels and, as far as the stratification and the limiting haulage gradients permit, to carry the panels forward on a straight bearing.

The coal mined is loaded into a mechanically driven oscillating conveyor which extends the whole length of the face and discharges into cars on the haulage entry. Here an endless rope brings the cars in trips to and

Fig. 4—Method of Working by Longwall Faces

Headings are driven so as to obtain an advantageous grade. Working faces are kept as nearly level as possible. Oscillating conveyors are used to move the coal to cars on the heading. Coal is broken down by means of drills, although experiments are being conducted with undercutters. This coal bed is about 40 in. thick.

Fig. 5—Headframes at André Dumont Colliery

European coal mines are built to endure. If a mine is expected to last for 200 years the headworks are constructed to last an equal length of time. Under such circumstances it is highly important to plan headframes and the like amply strong in the first place.

from the face. The coal is broken from the face by light jackhammer drills, no explosives or undercutting being required. Experiments, however, now are being made in the Campine field with various types of coal-cutting machines.

In a bed one meter (3 ft. 3½ in.) thick, eighteen men can break down and load into the conveyor, about 200 metric tons (220 net tons) of coal per shift of 8 hr., but this figure will probably be increased when transportation has been improved. Thus far the maintenance of haulage roads under the heavy roof pressure has proved a difficult problem at Winterslag, but it is hoped that relief will be secured as the face advances and the roof settles firmly on the waste filling.

Filling with waste is also a difficult problem for the mining engineers in the Campine. According to state regulations the workings must be completely stowed. In a longwall face, with an interval of 80 to 100 m. (262 to 328 ft.) between the roadways, the quantity of waste obtained in normal mining operations is insufficient to comply strictly with this regulation, and filling material must be brought in at considerable expense and inconvenience from some source outside the mine.

No doubt exemption from this regulation could be obtained, but, for the moment, the opinion prevails that complete stowing is necessary for safe working under the heavy roof pressure encountered. Hydraulic stowage has been suggested, but until the underground roadways are in a more stable condition, it would be risky to bring high-pressure pipe lines through them. Perhaps at some later date the orthodox longwall system, with side packs along the roadways and complete subsidence of the roof behind the face, will be tried.

If experience in British collieries can be taken as a guide this may ease the pressure on the roadways.

At Winterslag all underground transportation is by endless rope, the cars being attached in trips of forty or fifty. At some of the other collieries, however, it is proposed to use benzine (gasoline) locomotives. At one of the collieries in Holland, where conditions are similar to those in the Campine, a trial is being made with a storage-battery locomotive, and if its performance is

satisfactory the experiment is likely to be imitated. The chief obstacle to the use of storage-battery locomotives in the Campine is that in the initial stages of development the underground haulage roads are more or less unstable. The floor "creeps" a good deal, and it is difficult to maintain the tracks in proper alignment. Apart from this, however, the conditions seem to be ideal for battery locomotive haulage and it is quite possible that eventually this method of haulage will be adopted.

# How Output of Room-Slabbing Mines May Be Controlled

While Slabbing Pillars, Record Tonnage Is Obtained—When Driving Rooms, Output Is Low—Methods That Keep Output Steady

BY CHARLES GOTTSCHALK  
Consulting Engineer, Evansville, Ind.

EVER SINCE active interest in underground coal-loading appliances began, demand has grown for a type of machine that can load coal along a continuous face several hundred feet in length into a slowly moving trip of mine cars. The manufacturers have put forth every effort to meet this demand, and accordingly machines have been designed with swinging rear-end conveyors.

For various reasons, however, this has only partially solved the problem. The main outstanding difficulties encountered are the length of time required to develop the necessary modified-longwall faces, their comparatively short life, the control of the mine roof over wide worked-out areas and the need for a speedier means of developing room entries.

Many schemes have been proposed and tried with varying degrees of success. Some good layouts no doubt have been abandoned because of the immediate difficulties encountered. These resulted from attempting to control the roof in areas insufficiently large. Better results might have been obtained had perseverance been shown, for in that event a larger area would have been developed, thus providing more favorable conditions.

At the present time several operations are planning to increase production by driving rooms exceptionally long and then widening them out by successive slabbing cuts to a final width depending upon local roof conditions. This plan gives promise of affording a practical

Fig. 1—Mine Layout Adapted to Slabbing

Slabbing has just been completed in section A-1 and the short rooms in section A-2 are in readiness for the three loaders that have worked out A-1. Slabbing in B-1 has just been started by the three machines that drove the rooms to completion. Development of rooms in B-2 is to be finished when slabbing in B-1 is completed. The rooms in section C-1 are in process of driving and will be ready to be slabbed when slabbing is finished in B-1. When C-1 has been slabbed out territory will have been developed ready for slabbing in A-2, and so on. Fig. 2 shows the schedule of operation and estimated tonnage.

means for increasing the output of loaders beyond what could be obtained under normal room-and-pillar methods.

Room slabbing has been successfully employed in hand loading with exceptionally high output per loader together with an excellent low-fatality record. It is certain that all mine roofs are not suited to this method of operation but where it can be adopted the management will do well to consider this plan and the advantages to be gained thereby.

One of the difficulties first encountered in projecting a mine on this basis is the fact that room driving is much slower than slabbing. Thus should the loaders

TABLE I—Results Obtained with Various Operating Conditions in Slabbing Mine.

Layout	1	2	3	4	5
Estimated tons per 8-hr. shift per loader in room driving.....	125	150	150	150	150
Estimated tons per 8-hr. shift per loader in room slabbing.....	250	300	300	300	300
Width of room before slabbing (coal 6 ft. high).....	22 ft.	22 ft.	22 ft.	22 ft.	22 ft.
Length of room beyond first room parting.....	450 ft.	450 ft.	450 ft.	450 ft.	450 ft.
Number of slabbing cuts from one side only of each room.....	3	3	4	5	6
Final width of rooms after slabbing.....	40 ft.	40 ft.	46 ft.	52 ft.	58 ft.
Final width of room pillar remaining.....	18 ft.	18 ft.	18 ft.	18 ft.	18 ft.
Required number of feet of room entry to develop one section.....	672 ft.	840 ft.	930 ft.	1,020 ft.	1,110 ft.
Required number of calendar days to develop one section.....	112 ft.	112 ft.	112 ft.	112 ft.	112 ft.
Number of 8-hr. shifts per day required on development.....	1	112 day shifts 28 night shifts	112 day shifts 43 night shifts	112 day shifts 58 night shifts	112 day shifts 73 night shifts
Number of days per section on room driving.....	75	75	75	75	75
Number of days per section on room slabbing.....	37	37	37	37	37
Length of slabbing area = length of room driven on development + room extension.....	520 ft.	520 ft.	520 ft.	520 ft.	520 ft.
Average daily output from sections A, B & C.....	1,500	1,800	2,100	2,400	2,700
Average daily output from each machine.....	166	200	210	218	225

Note: Production from entries not considered. Extra loaders in conditions Nos. 3, 4 and 5 to work continuously on slabbing being transferred progressively with slabbing operations.

In Layout No. 1 three mechanical loaders are employed in entry A, three in entry B and three in entry C; there being twelve rooms in each section. Nine loaders are provided for the three "room sections." In Layout No. 2 there are three mechanical loaders employed in entries A, B, and C respectively, as in Layout No. 1, but there are fifteen rooms in each section. As before there are nine loaders for three "room sections." In Layout No. 3 the conditions are the same as in Layout No. 2, except that the slabbing is performed one more time

than in the Layout No. 2 and one extra loader is provided for three room sections. In Layout No. 4, the conditions are as in Layout No. 2, but two more slab cuts are made, that is, the slabbing is carried 12 ft. further. Two extra loaders are provided, so there are eleven loaders for three room sections. In Layout No. 5 again the conditions are as in Layout No. 2, but here 18 ft. more is slabbed off the pillar than in Layout No. 2; three extra loaders or twelve in all are used for the three room entries.

have twice the tonnage in slabbing that they have in room driving, the total output from a number of machines will vary from day to day according to the number of places available for the more advantageous loading. For example, a certain section might produce 500 tons per day for 20 consecutive days, then 1,000 tons per day for 10 days, then drop back to 500 tons again and repeat the cycle. This state of affairs if not balanced from some other source would be highly disconcerting to the sales organization.

#### UNIFORM STANDARD OUTPUT APPROXIMATED

To assume a probable case, it is possible to make a layout so as to anticipate the objection mentioned and standardize on a certain average daily output. If this is done, the transportation problem will be similar from day to day. Likewise, the average output per machine may be calculated in a more satisfactory manner.

In the accompanying figures, in the captions of which brief explanations have been incorporated, an attempt has been made to demonstrate at least one method of arriving at a concrete working plan that will bring about a constant daily tonnage where both room driving and room slabbing are employed.

Five different sets of conditions have been considered, as outlined in Table I, and the plan and equipment theoretically adjusted to each. No dimension, be it room width or length, has been assumed without considering its relation to the average capacity of the loaders and the thickness of the coal worked. Both these conditions will vary in different localities, but they must be determined accurately before the most advantageous layout can be planned. This is none the less true for hand loading.

Taking account of tonnage, the question of what a loader will do under various conditions and what this or that mine is getting from them are two distinct considerations. It has been amply demonstrated that machines are on the market that will load two tons of loose coal per minute, be it slack, run-of-mine, or lump. The quantity that machines are actually loading under practical working conditions in the mines is, generally speaking, the measure of the ability of the mine management to produce loose coal at the face and transportation to remove it therefrom.

#### CAN SHOOT COAL HEAVILY YET INEFFECTUALLY

The opinion has been expressed that in order to obtain satisfactory coal for mechanical loading it is necessary to resort to heavy blasting, thus increasing the percentage of fines. On the contrary, holes improperly placed and overcharged often result in a fall of coal which, although so shattered as to leave little if any lump, is so tightly wedged between the room ribs that a mechanical loader cannot economically dislodge it.

Accepting this fact then, that machines have been perfected capable of satisfactorily loading loose coal at the rate of several hundred tons per eight-hour shift,

Fig. 2—Graphic Operating Schedule for Keeping Track of Slabbing Mine

By planning the slabbing cycle as illustrated the tonnage obtained in any day throughout the entire production period remains constant. Once a territory has been developed according to this plan,

there should be, under normal conditions, no interruption to or decline in output until arrival at the boundary of the assigned area. A practically uniform output is thus assured.

it certainly would appear logical to spend time and money commensurate with the possibilities involved to develop a mining process that will suitably prepare the coal for a light and portable loader, various types of which are already on the market.

### What Shall We Do When Coal Is Gone?

At a session of the British Association for the advancement of Science held in Toronto, Ont., Prof. F. G. Donnan, of University College, London, said that when coal and oil are exhausted new forms of fuel will be obtained from common salt. Where water power exists near beds of salt (sodium chloride) the power will be turned into electricity and used to obtain chlorine from the salt, the chlorine gas to be transported to industrial centers for fuel.

J. Alexander, a New York chemist, proposed the alternative solution that water-generated electricity should be used to break up water into hydrogen and oxygen, using both gases for heating, and perhaps also using the hydrogen in internal combustion engines. It was pointed out that millions of horsepower were going to waste because of difficulties of transmission which might be overcome by either of the two schemes suggested.

Neither suggestion seems as likely to be effective as the transmission of electricity in view of the expense of transporting gases even in pipes.

### Utah Fuel Co. Makes No. 2 Mine Safe

On July 21 the Utah Fuel Co. reopened No. 2 Mine, where on March 8 a disastrous explosion occurred killing 171 men. B. W. Dyer, of the U. S. Bureau of Mines, with other experts made a thorough inspection before the reopening, reporting that an analysis of the return air showed 0.12 per cent of methane and a volume of 175,000 cu.ft. of air per minute. The mine liberates about 300,000 cu.ft. of methane every twenty-four hours. Every place in the mine is well ventilated. All working places and practically all places opened in the mine have pipe lines extended to the face so that every portion of the mine can be wetted down, and the places which are to be operated are equipped so that the men working there can keep their places wet.

Rock-dust barriers have been placed in right and left entries off the dips. Telephones are being installed throughout the mines. Company men will load and tamp all holes after the men are out of the mine and shots will be fired after everyone, shotfirers included, have reached the surface.

*Power Plant of Susquehanna Collieries Co., Lykens, Pa.*

## Susquehanna Collieries Co. Burns Pulverized Anthracite Slush at Lykens, Pa.

One of the First Power Plants to Utilize Anthracite Slush in Pulverized Form—Coal Mixed with 75 per Cent Water Pumped to Plant—Boiler Plant Contains Six 5,000- and Six 6,000-Sq.Ft. Water-Tube Boilers—Present Generating Capacity 6,400 Kw.

**T**HE successful application of pulverized coal in the firing of stationary boilers and the ability to burn in pulverized form practically any and all grades of coal with an approximately equal degree of thermal efficiency, have brought about the recent utilization of coal that heretofore had practically no market value.

Constituting a large percentage of this class of coal is the small-sized anthracite (smaller than No. 3 buckwheat) which up to a recent date was considered waste incident to anthracite mining and was in many cases allowed to be washed into nearby streams.

The accumulation of this fine coal has been going on many years until mountains of this material are piled around the collieries. The beds of the rivers and creeks are also lined with the material. The total quantity, probably running to nearly one hundred million tons, has washed down from the mining regions.

As all fine anthracite is referred to generally as culm, it might be well before going farther to point out the difference between culm and slush. A culm bank, as it is known in the mining region, contains all waste products from a colliery and consists of, depending upon its age, any coal that was rejected as unmarketable at the time, with slate, rock, breaker refuse and in the majority of cases ashes from the boiler plant. A slush bank consists entirely of coal relatively free from any rock or slate, but so fine as to be unmarketable; the fine reject from breaker or washery; a coal passing the smallest coal screens, sometimes called sludge and silt

from its condition when wet. Slush is being made at the present time from all breakers and washeries that are re-treating culm banks.

The new power plant of the Susquehanna Collieries Co. erected in 1920 and 1921 to supply current to its Short Mountain and Williamstown collieries, was the second commercial installation to use anthracite slush in powdered form, the first and smaller installation having been built by the same company at its Lytle colliery in 1918.

### EXISTING PRACTICES WERE HIGHLY EXTRAVAGANT

At the time this plant was put into operation, the steam for operating the Short Mountain colliery was being supplied by three boiler plants with a total of nine water-tube boilers of 5,000 sq.ft. of heating surface and three locomotive-type boilers of 1,000 sq.ft. of heating surface. At the Williamstown colliery five boiler plants were in operation, containing a total of fourteen water-tube boilers of 5,000 sq.ft. of heating surface and three locomotive-type boilers of 750 sq.ft. of heating surface. The combined operating forces of these eight plants, including firemen, water tenders, ash men, coal passers, boiler cleaners, etc., totaled 154 men, and the coal consumption for the year 1917 amounted to 203,631 tons, the average boiler efficiency in these plants being around 35 to 40 per cent. The fuel burned was all commercial coal, about 90 per cent of which was No. 3 buckwheat and the remainder No. 2.

During the latter part of 1917 an exhaustive study

was made as to a means of reducing the power cost at the several collieries of the company, and this led to an investigation into the possibilities of burning anthracite slush in pulverized form in the new power plants which constituted part of the program of rehabilitation.

At this time the problem was discussed with the Fuller Engineering Co. and the mining company made an appropriation for an experimental plant consisting of a 2,500-sq.ft. Babcock and Wilcox boiler, a 42-in. screen-type pulverizing mill and a rotary drier that the mining company had on hand. This research work was continued from the latter part of 1918 to the end of 1920 under the supervision of R. M. Walker, consulting engineer of the mining company, with C. W. Lotz, combustion engineer, in direct charge of the work, and it might be stated that the ultimate success of burning pulverized anthracite is largely due to his work.

the fuel to ignition temperature after leaving the burner in the furnace proper, and also demonstrated the importance of introducing the coal into the furnace in the form of a narrow curtain, which method, it might be recalled, has since become more or less standard practice.

With these preliminary studies completed and the possibilities of a material saving in power costs assured, it was decided to adopt this method of firing in the new plants for which plans were already under way.

#### PUMPING SLUSH CHEAPER THAN CONVEYING

The slush, with a consistency of about 25 per cent coal and 75 per cent water, is pumped from the breaker and washery a distance of approximately 2,500 ft. and against a head of 400 ft., to a point on the side of the mountain adjacent to the power plant. It may appear

Fig. 5—Cross-Sectional View of Boiler, Furnace and Setting

The 45-deg. slagging shelf recently has been removed. Changes made in the combustion chamber are indicated by dot-and-dash lines. The boiler headers are approximately 13 ft. above the floor of the combustion chamber. Long narrow burners are located in the top of the front extension of the walls.

For this experimental work the combustion chamber was extended out in front of the boiler about 32 in., and was made the full width of the boiler and about 9 ft. deep, with approximately 13 ft. between the boiler headers and the combustion-chamber floor.

The first trial was made with a round-type burner located in the furnace front about 6 ft. from the bottom. As this resulted in heavy slagging and destruction of the ignition arch and brickwork of the rear wall, further experiments were made with several types of improvised burners located at different elevations in the furnace front, the final trial being conducted with a long, narrow burner constructed of sheet iron and placed in the top of the combustion-chamber extension. The secondary air in all cases was introduced through openings in the rear wall directly above the furnace bottom. These experiments showed that low-volatile fuels could be burned only in suspension by preheating

that much power is expended in pumping 3 lb. of water to each pound of coal over this distance, but as the slush leaves the breaker and washery with waste water, it was considered more economical to pump the water and slush to the plant and then dewater it than to convey the solid coal the same distance.

At the plant the coal is first discharged into two dewatering devices consisting of two concrete tanks and four slow-moving drag scrapers. The latter remove the coal from the tanks and discharge it directly to two coal stackers, one of which is shown in Fig. 3.

The stackers, each of which consists of a 90-ft. boom carrying a drag scraper, were developed in the consulting engineering department by E. B. Worthington, mechanical engineer, and provide a practical and economical means of storing coal.

The lower side of the trough in which the scraper carries the coal is fitted with a number of sliding gates,

Fig. 1—Screw Conveyors Operating Over the Pulverized-Coal Hoppers

Fig. 2—Coal Bunkers and Screw Feeders Above Operating Aisle

Fig. 3—One Unit of the Dewatering and Coal-Stacking Equipment

Fig. 4—Central Boiler Operating Aisle; Six Boilers on Each Side

Fig. 6—Two 3,200-Kw. Turbine Units

The present generators consist of two units but sufficient space is available for a 7,500-kw. turbo-generator which will make this mine power plant one of the largest in the region and even larger than many public utility stations.

permitting the coal to be discharged at any point along the boom. The boom is arranged to swing through an angle of 180 deg., and this provides facilities for stacking approximately 100,000 tons with the two units in operation. The general arrangement of the dewatering and stacking and reclaiming equipment is shown diagrammatically in Fig. 9. Upon leaving the stacker the coal contains about 30 per cent moisture, but after standing in the pile for about 48 hours the moisture has decreased to around 10 per cent.

The reclaiming of the coal from the storage pile is accomplished by a scraper bucket operated from a motor-driven drum hoist, suitable anchor posts being arranged around the pile. The drum hoist is mounted on a turntable with a central discharge, and this feature permits swinging the drum in line to suit any position in which the scraper may be required to operate, the entire operation of dewatering, stacking and reclaiming the coal requiring the services of only two men.

From the discharge hopper of the drag scraper the coal is conveyed by a scraper-type conveyor to a distributing conveyor above the raw-coal bunkers in the pulverizing house. From the bunkers it is passed to two 25-ton per hour double-shell driers, hand-fired. Passing through the driers, the moisture in the coal is reduced to about one per cent.

#### EIGHT PULVERIZERS OF TWO TYPES EMPLOYED

The coal as discharged from the driers is elevated into a concrete dry-coal bin located over the pulverizing room and arranged with suitable discharges to eight 42-in. screen mills, four of which are belt driven from vertical motors and four geared-type direct connected to horizontal motors.

The screen test of the slush as fed to the mills runs about 70 per cent through a  $\frac{3}{4}$ -in. screen, and the finished material leaving the mill runs about 82 per cent through a 200-mesh. It may be recalled that this is a much finer product than is generally considered necessary with bituminous coal. This fine grinding, however, appears necessary with anthracite slush in order to obtain proper ignition owing to the low volatile content of 8 per cent as compared with bituminous coals having 30 to 40 per cent volatile.

The mills discharge the pulverized coal into screw conveyors, which in turn feed into duplicate systems of bucket elevators which carry the coal to a point

above the boiler bunker level whence it is conveyed by duplicate screw conveyors to the fuel bins above the boiler aisle. As each conveyor is fitted with discharge chutes to each fuel bin, as shown in Fig. 1, one conveyor only is operated at a time, thus leaving one as a spare. The total capacity of the pulverized-fuel bins is approximately 250 tons, or a supply sufficient for a 24-hour full load of the station.

Referring to Fig. 4, the boilers are arranged in two rows, with six boilers on each side of the operating aisle. There are six 5,000-sq.ft. horizontal water-tube boilers equipped with superheaters and operated at 190 lb. pressure, and six 6,000-sq.ft. boilers of the same type without superheaters operating at 145 lb., all the boilers being designed for 200-lb. working pressure. The normal pressure of 195 lb. carried on six of the boilers was selected to suit the main generating units, and the pressure of 145 lb. carried on the remaining boilers was governed by the local colliery, in which there are two 48x72-in. hoisting engines and two 3,000-cu.ft. steam-driven air compressors and underground pumps. Provision has been made, however, for operating any of the boilers on either service by making the steam header in the form of two connected loops with sectionalizing valves between each boiler.

A cross-section of the furnace and boiler setting is shown in Fig. 5. The combustion chamber is extended out in front of the boiler sufficient for a good burner setting. It will be seen that the design of the combustion chambers is a departure from the usual practice. The floor of the chamber slopes at an angle of 45 deg. from the bridge wall to within 4 ft. of the front wall, the narrow portion at the front of the chamber serving as an ashpit. On the 5,000-sq.ft. boilers the furnace volume is 1,531 cu.ft., giving a ratio of square feet of heating surface per cubic foot of furnace volume of 3.26. On the 6,000-sq.ft. boilers this ratio is 3.76.

The ashes are removed from the pit by sluicing, the discharge from the mine pumps being used for this service. The bottom of the pit slopes from the side walls into a trough at the center. Water is led into the furnace at each side wall and flows down the inclined floor, carrying the ash with it. From the central trough the ash is washed out through a swinging door to a common duct below the central aisle and discharged into a suitable space outside the building. The sloping floor of the ashpit is grooved in order to reduce the water surface exposed to the radiant heat of the fur-

nace. The heavy dot-and-dash line shown in the section Fig. 5 indicates the change recently made in the combustion chamber of one of the boilers, but at the time of writing no tests have been conducted to determine what improvement has been made in the efficiency of the boiler.

Each boiler is fired by one burner located in the arch forming the top of the combustion-chamber extension. The opening in each burner is approximately 2½ in. wide by 5 ft. 2 in. in length. Each burner discharges directly against a hinged deflector (see Fig. 8), the position of which is controlled by a chain wheel and screw operated from the floor. In this way the flame travel can be adjusted to suit the load condition. Provision is also made in the cast-iron housing surrounding the burner for admitting secondary air, a damper being fitted to the top of the housing and operated from the floor.

SIX BOILERS IN A ROW SERVED BY ONE STACK

The feeders, two for each burner, are mounted directly below the pulverized-fuel bins with the controls conveniently located on the boiler fronts. The primary air is supplied by two motor-driven fans located between No. 3 and No. 4 boilers of each row and discharging midway into the primary air header, which is carried along the length of the boiler room directly above the operating aisle.

Each row of six boilers has a single stack with two breechings, the former in the center with three boilers on each side. The stacks are radial brick 12 ft. in diameter at the top and rise 175 ft. above the base.

The present installed turbo-generator capacity is 6,400 kw. in two units of 3,200 kw. each, provision being made in the station layout for an additional unit of 7,500 kw. The condensers are of the jet type and are mounted directly below the turbine exhaust, a spray pond being used for cooling the injection water.

The feed water to the boilers is supplied by three

Fig. 8—Pulverized-Coal Burner and Spreader

Each burner discharges against a hinged deflector which permits the direction of the flame to be varied as the load changes. Secondary air may be admitted to the burner housing by means of a damper controlled from the floor.

centrifugal pumps, two of which are motor-driven and one steam-driven. The pumps are in the turbine-room basement directly below the feed-water heater. Exhaust steam for heating the feed water is supplied by the removal pump of each condenser and the discharge of the rado-jet air pumps. The exhaust of the two 3,000-cu.ft. air compressors at the colliery is also returned

to the plant, and any excess then is exhausted to the air.

The preparation plant is operated during the sixteen hours off-peak period that the collieries are idle. During this time sufficient coal is prepared for the twenty-four hour operating period of the station.

The cost of preparing and handling the coal at the Lykens plant averages about 60c. a ton over a twelve-

Fig. 9—Fuel Transporting and Dewatering Equipment

Water and slush from the breaker and washery is pumped into two concrete tanks from which the coal is removed by two coal stackers. From storage it is taken to the pulverizers.

month period. This includes operating and maintenance, labor and supplies, including power and superintendence, but not investment charges. The cost of pulverizing alone is about 24c. a ton.

The cost of preparing and handling the coal here given may at first appear high, but when it is remembered that the plant is being operated considerably below capacity, and that the cost of pulverizing and the maintenance charges on the mills increases rapidly with the degree of fineness of pulverization and the percentage of ash (the coal in this case is pulverized to a fineness of 82 per cent through a 200-mesh screen and contains 20 per cent ash) and that the pulverized coal is conveyed a distance of 500 ft. from the preparation plant to the bunkers above the boilers, this cost is not excessive.

The plant was designed and constructed under the direct supervision of R. S. Walker, consulting engineer of the M. A. Hanna Co. of Cleveland, which operates the Susquehanna Collieries Co., and his associates, A. J. Cayia, his assistant, E. B. Worthington, mechanical engineer, C. H. Matthews, electrical engineer, and C. W. Lotz, combustion engineer. Co-operating with these were H. L. Reese, electrical engineer, and W. E. Weinck, construction engineer, of the office of R. A. Quin, manager of the Susquehanna Collieries Co. at Wilkes-Barre, Pa., and E. A. Van Horn, superintendent of the Lykens Division of the same company. The plant is operated under the direction of H. B. Jones, chief station engineer. The H. C. Felver Co., of Cleveland, Ohio, constructed the plant.

## Keen Interest in Mechanical Loaders Signalized Meeting of Institute at Rock Springs, Wyo.

Shovel Propelled by Hydraulic Ram with Frame Held to Its Work by Water Pressure Said to Have Remarkable Digging Qualities—Mine Fires and "Hush! Hush!"

Policy Discussed—Committee Advocates Sprinkling!

**N**EXT TO ROCK dusting, mechanical loading methods and equipment elicited the principal attention of the members of the Rocky Mountain coal Mining Institute at their summer session, Aug. 7-9, in Rock Springs, Wyo.

Machine loading has reached a fairly high point of development at the Union Pacific mine at Hanna, Wyo. Superintendent T. H. Butler described the operation of Joy and Thew loaders in the 32-ft. seam of lignite at No. 4 mine. Joy machines load out the lower 8 ft. of this coal from 32-ft. rooms driven on the strike of the seam which pitches from 14 to 17 deg. Eighteen feet of the remaining 24 ft. are shot down and loaded out by the Thews. The Thews are operated by one man on the machine and two trimmers. Four men are used with each Joy, because the large lumps have to be broken and the tight coal has to be pulled down. Fewer men than this would greatly reduce the tonnage. The Thews are averaging 240 tons a day and the Joys 104 tons.

Mr. McAuliffe, president of the company, supplementing Mr. Butler's paper, said the Thews are money makers for the company, loading coal for 52.4c. per ton, which is a saving of about 30c. a ton. The Joys load at a cost of 72c., which is a saving of 11c. He said the Joys helped to make the Thews good earners for the company.

At the Reliance No. 1 mine of the company two Joy machines working in rooms on fairly steep pitches are able to average only about 72 tons daily, but in spite of handicaps they are cutting at least 1c. a ton from

the cost of loading. The institute visited this mine and saw these machines work.

Mr. McAuliffe took a rap at the institute members for not being franker and more liberal with the whole truth of every subject discussed. He said his company is perfectly willing to tell anybody anything about Union Pacific practice that will help them in coal-mine operation and he hoped other members of the institute would do the same thing.

Secretary Benedict Shubart replied that machinery men in the institute were "sales engineers" not "peddlers" and cannot in decency tell what they know about the results attained by mining companies. He said the companies must reveal their own results, if the mining public is to be informed.

The discussion then veered to the question whether loading machines increase slack. Mr. Butler said that the Union Pacific Coal Co. did not keep such data, for all the company's mines produce mine run. However, he does not think the slack proportion has been increased at Hanna. C. M. Goddard, representing the Joy Machine Co., said it is the shooting of the coal and not the machine itself that increases slack.

The coming of loading machines is going to produce at least one important change in mine operation, said T. H. Stroup, Superintendent of the Clear Creek mine of the Utah Fuel Co. It will make the operator take full responsibility for what takes place at the face, and at that point, he said, is to be found the heart of most mining problems. Heretofore, he remarked, there has been too great a tendency to blame everything at the face upon the miner.

In coal mines he thinks about 75 per cent of the men have been attaining only about 50 per cent efficiency,

NOTE—Headpiece shows Rocky Mountain Coal Mining Institute presenting solid front to photographer at Rock Springs, Wyo. A previous article on the meeting of the institute appeared Aug. 14 on pp. 227-229 entitled "Rocky Mountain Men Strike New Note in Dusting."

for that very reason. Coal could take a leaf from the book of metal mining in this particular, for there Mr. Stroup has observed much closer attention paid by the company to face operations. As a result, loading at some big metal mines costs only 16c. a ton, yet loaders are happy, for they are making \$35 a week. They are kept busy, and their tonnages are high. Regular periods of rest are provided but the mines are operated so systematically that loaders lose no time needlessly.

Adaptation of loading machines to present systems of mining and not a radical revolution of methods to fit machines, is what S. W. Farnham, chief engineer of the Goodman Manufacturing Co., looks forward to as he scans what appears to be the future of underground loading. He told the institute that the famous V-system and some other efforts to attain tremendous tonnages do not look good to him because of the difficulty which must be met in cleaning such volumes of coal.

His idea of the proper loading machine is either a machine that merely loads and must have all its digging and loosening of coal done for it, or else a big strong digging machine which actually will tear loose tight coal thus producing more big lumps with less shooting. Any machine in the middle ground between these two extremes, will fail he thinks. The fact that so many mining men appear to expect digging of middle-ground machines is one reason why many machines that are already in the field have been scrapped.

Mr. Farnham holds that mechanical loaders cannot replace hand labor. Even hand loaders seldom actually load coal over half their working time. The rest of the time is devoted to track work, loosening tight coal, trimming cars and a score of other activities. He cannot see how loading machines ever can be expected to load all the time.

For that reason he does not believe that machine pay ultimately will be on a day basis as it is now in most of those states using machines. When it is on a tonnage basis, the time consumed in work around the machine will be less and the machine will load its maximum tonnage. During these days of experimentation with machines, however, he recognizes that daily wages may be best because tonnage scales fixed now might be extravagant for the machines which eventually may be developed. Scales once established in union fields are hard to change.

He reported to the institute that, after visiting most of the loading operations in the country, he estimated that the average tonnage being loaded by machines is about 70 tons daily and that the greatest limiting factors are breakdowns and the difficulty of getting cars to and from the machines.

Reverting to the V-system, he said the disadvantages were high cost of installation, difficulty of moving the equipment, danger of crushing at the face, the necessity of changing the whole system of mining, the difficulty of hand loading large lumps into conveyors and the need for extensive supervision.

Mr. Farnham described to the institute the new Goodman shoveling machine and showed pictures of it. The machine is about to be put on the market after extensive trials in a salt mine in New York state. It loads with a large shovel propelled by a hydraulic ram. This shovel, which is operated from a revolving turret, discharges coal gently into cars by the forward propulsion of the rear wall of the shovel. The machine is prevented from sliding backward by a hydraulic prop which is readily adjusted against roof and floor. It requires 6 ft. of headroom.

Charles Gottschalk, of Evansville, Ind., described what Indiana had learned about mechanical loading where a number of companies have been working various types of machines. One of his conclusions was that, until loading machines attain high daily tonnages, the problem of getting cars up and away from the machine is much less of a factor in production than that of proper shooting.

Mine fires give much trouble at the Reliance mines of the Union Pacific Coal Co. Superintendent Thomas Foster described various methods that have been used to check them. In one fire zone an effort to load out the fire failed, so sand packs were tried. They were built of timbers and boards behind which was left a space of 2 or 3 ft.

between the wooden wall and the coal rib. This method gave good results except that the sand tended to settle and had to be watched at the top.

The same method is being used to check another fire which previously burned across entries in the top coal and otherwise insisted upon spreading. Water poured through holes drilled in from the surface was of no avail for, when the water struck the hot rock over the burning coal, the rock turned to mud and choked the hole. The top coal is now taken down in entries which the fire is approaching, and sand packs are built to the cap rock. Fires in the Reliance mines from 1915 to 1924 cost \$118,681 or a shade over 3c. per ton of output. George Brown of Cumberland, Wyo., who has been battling bumps in the Union Pacific mines at that place since 1918, recited some of his experiences.

Eugene McAuliffe, president of the Union Pacific Coal Co., appealed to the mining fraternity to know more and guess less in the business of operating mines. He thinks there is altogether too much rule-of-thumb practice and too many men are bound by precedent and custom. Many mining men are satisfied with their ventilation if they think they have the right size and type of fan, the proper air input and water gage. But do they know definitely that enough air reaches the face? Mr. McAuliffe doubts if they do.

He questions whether they maintain ventilation maps of their workings and keep definite records of air delivered to the active spots in the mines. He doubts also if the average mining man realizes that if one per cent gas content is shown in an analysis of the return air from a mine supplied with 100,000 cu.ft. of air per minute, the total gas generated in that mine daily is no less than 32.47 tons. This may be harmless enough

### McAULIFFE ADVOCATES LESS SECRECY

**T**HOUGH the Union Pacific Coal Co. under Mr. McAuliffe's leadership and that of his predecessors has made great strides in the adoption of new methods, he believes the mining public should receive the full benefit of the results of all the pioneer work done in those mines and elsewhere and calls for more frankness in describing operating results, that industry may progress and every one may be benefitted. The Union Pacific Coal Co. at the Rock Springs meeting gave much information regarding its practices in mine fires and machine operation.

when diluted in the proportion of one to 99 with air, but who knows positively that his ventilation system is adequate at all parts of the mine to make that dilution? Proven facts is what Mr. McAuliffe thinks the coal industry needs, and he appealed to the institute for closer adherence to them.

#### COMMITTEE NOT ORTHODOX ON DRY ISSUE

The institute adopted without debate the report of the institute's safety committee, over which there was some hot argument at the winter meeting in Denver. The report condemned shooting off the solid, opposed the use of black powder in any mine where coal is cut or sheared and urged that no shooting be done when men are in the mines. It favored electric safety lamps in every mine that shows gas. It advocated careful use of water on cutter bars, better protection of bare wires and electrical equipment. It charges "at least 25 per cent of present-day explosions" to electricity.

The report proposes a long list of methods and devices for making ventilation more thorough and dependable.

To reduce dust it suggests that under certain conditions longwall be used instead of room-and-pillar mining, advocates more shot holes and lighter charges and that water be sprinkled regularly on roadways and on loaded cars. It recognizes the value of humidification of intake air by steam but does not insist upon its general adoption because of the expense accompanying the introduction and operation of such installations.

The report advocates rock dusting in mines having dangerous dust or both dust and methane. It opposes the installation underground of any electrical equipment or apparatus that is not approved by the Bureau of Mines.

"Miners rarely have any adequate idea of what constitutes safety in coal mines" reads the report, "and this applies equally to the experienced miner and to the man who has worked in the mines only a few months." So an extensive campaign of education is advocated, to be supported by mining companies, in conjunction with the government and the states. The report also covers many other points of lesser importance.

### Where Do Safety Bulletin Boards Attract Most Attention?

**M**INE managers, chiefly through the preachings of safety men and institutions, are well aware of the value of bulletin boards as a medium of educating the miner in safety; but in most cases they do not place the bulletin boards where they will be most read. C. E. Reynolds, superintendent of the Springdale mine of the Allegheny Pittsburgh Coal Co., near Pittsburgh, claims that the most frequently read bulletin boards are those that are posted at the junctions of main manways in the mine and at the important corners of streets in the mining town.

When miners are on their way in the mine to or from work, each time they pass a bulletin board at an important junction point their attention is attracted, for a moment at least, to the illuminated bulletins. Old bulletins which they have passed day after day register no distinct impression upon them, but—"What hold a new series of bulletins; let's stop and read them." That really is the psychological effect of brightly lighted

educating miners in safety. It is she who worries more than the man over his life and limb while at work in the mine, for her bread and butter and that of her children, if she has any, depends upon his

**Bulletin Board in Mining Town of Logans Ferry**

It is just as important to educate women and children to safety as it is to teach the men, for the former have a strong influence on the latter. It is wise to post a number of such boards in each mining town.

**Illuminated Safety Bulletin Board**

This bulletin board is certain to attract attention, for it is located on a much-traveled manway. These men are leaving the mine after a day's work. If one of them stops at this point for his "buddy" who may be farther down the line, he is likely to read the bulletins. Note the cleanly swept bottom along this manway. It is kept equally as clean for miles.

bulletin boards in the mine. The same boards in daylight in and around the bathhouse, at the shaft or pit-mouth, are passed unnoticed.

Woman can be made to play an important rôle in

employment every day that the mine runs. It has been observed time after time, that a man who is injured in a mine accident quarreled with his wife before leaving home that day. Her quarrels with him often are an indirect cause of his being injured, but fortunately if she is the right kind of wife she has an equally strong influence in making him careful.

Knowing this, Mr. Reynolds has erected several bulletin boards on the streets of the village of Logans Ferry. During the day the women and children are often seen reading the bulletins, which if placed about the mine plant would not come under their observation. At night man and wife, when walking together, are attracted to the lighted bulletin board led by the greater curiosity of the women, and the husband gets a brief lecture on safety whether he wants it or not. More bulletin boards should be provided in the mine and in the town.

# How Should Loading-Machine Workers Be Paid?

Here Is a Presentation of the Arguments on Both Sides of the Case—for a Tonnage Scale and for a Daily Wage—by T. A. Stroup, Mine Superintendent, and S. W. Farnham, Mining Engineer

*Ever since machines were devised for underground loading of coal, authorities in the industry have differed on the question: How should loader operatives be paid? The United Mine Workers officials, thinking that thereby the men would get a bigger share of the benefits from new mining machinery, have held out for tonnage rates. Operating men have taken both sides, but mainly they have favored day wages. Thus far in the development of loaders the operators have had their way, but the day scales now in effect in all union fields of this country are fairly high. In Illinois and Indiana the scale is \$10.07—although only Orient No. 2 mine is working the machines in Illinois—and Wyoming's rate is \$11.50.*

## Tonnage Pay Is Coming

"Loading machine operation eventually is sure to be paid for on a tonnage basis, I believe," said Mr. Farnham, "because, by that method of compensation, the machines are most likely to be worked nearer to their full capacity and, as another important factor, the attendant work around a loader will be more expeditiously done. There is no need to expect any loading machine to be operated steadily eight full hours every day. It simply cannot be done. No matter how good the machines of the future are, there always will be much necessary work connected with their operation, other than the running of the machine and this will always cause delays. Why even where loading is all done by hand, the men spend only about half their time actually shoveling coal into pit cars. How can it be greatly different when machines do the work?"

"So, bearing in mind that fact that there is, and always will be, a good deal of this sort of labor—trackwork, or moving of conveyors, shifting the loader about, cleaning up coal that overflows the car or misses the conveyor, loosening tight corners and a lot of other essential jobs—isn't it fair to assume that the miner who is paid only for the number of tons he loads is going to see that the loading goes on the maximum number of minutes? And if he is paid by the day, he will not be so speedy with all this aside work, will he? That is why I believe the tonnage basis will be adopted some time, although the time for it has not yet come.

"There is sound logic in the argument that tonnage scales ought not to be fixed right now, because the loading machine is developing fast and scales that are fair today would be outlandish tomorrow. But we should not get the idea that tomorrow or next year or five years from now is going to see the culmination of loader development. I don't think we will ever reach a point where we can say: 'Now we have the loader; it is time to make a tonnage scale.'"

*Most operators of the country foresee the adoption of loading machines before long in almost every mine. Therefore, the question of wage scales is vital. Two interesting views on the issue were expressed recently in the West by men of life-long experience in coal and whose opinions are respected the country over. T. A. Stroup, superintendent of the Clear Creek Mines of the Utah Fuel Co., believes in the day wage and is sure the country will stick to it. S. W. Farnham, mining engineer of the Goodman Manufacturing Co., believes a tonnage scale will inevitably be adopted for the reasons he sets forth, although he would like to see the day wage perpetuated. Here is what they say:*

## Case for the Day Wage

"I believe in the day wage for loading-machine operators," holds Mr. Stroup, "for several reasons, but the main reason is just this: Loading machines are going to force mine operators to assume full responsibility for what goes on at the face instead of passing the buck to the miner. This means men working at the face are going to be under more direct supervision—which will be easier with machine loading than it is now because of the future concentration of men working in few places.

"This concentration of men is going to play an important part. I am morally certain that the average miner would do more work if he were in a group than he does when he works alone; but even if this psychology failed, there is another important reason why the miner working around a loading machine at the face—and every other man in the whole mine, for that matter—will do more in a day than he does now. He is going to be a necessary cog in a machine. What he does depends upon what every other man in the system does, and what the others do, depends upon him. Don't overlook that.

"This is exactly the thing that makes the plants of Henry Ford such astonishing producers. The employers have devised systems of production which raise to the nth power the factor of interdependence of the workmen. There is a lot of facts at the base of those funny stories about the Ford employee who got fired. When somebody asked him why he lost his job, he replied that he dropped his wrench and before he could pick it up 865 cars had gone by him with the nuts that he should have tightened loose on their threads. They may be telling stories like that on the coal miner after awhile. The operator is being forced right now to develop a much better system in his mine. Heretofore he has been watching the tippie and selling the coal and damning the miner if the coal didn't come out. Hereafter, with money tied up at the face in loading equipment, he will devise ways of running every minute."

## News Of the Industry

### Consolidations and Consumer Ownership Stabilizing the Coal Industry

Many Transactions Being Quietly Consummated—Northwest Should Buy Coal or Consequences May Be Serious—Too Much Optimism Among Producers

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Two developments of far-reaching importance are in progress in the coal industry. Consolidations have been effected and are in course of consummation almost sufficient to constitute evolution. The number of captive mines is increasing by leaps and bounds.

When the Harding Coal Commission made its report, in which consolidations were recommended, there was no way of foreseeing that an economic situation would develop within a year which would bring about consolidations to an extent far beyond any hope the Commissioners may have entertained at that time. Under the compelling pressure of slack demand and the prospect of a long period of uninterrupted production increasing numbers of high-cost mines had been forced upon the market.

As many of these transactions are kept as quiet as possible and because there is no centralized point at which figures covering such transfers are available, there is no accurate knowledge as to the extent to which this tendency has progressed. Those in the best position to judge express the belief that the more powerful companies have absorbed a larger number of high-cost mines than is generally supposed. If current rumor has foundation several large deals of this character are about to be consummated.

Before the end of the year, it is predicted, enough mines will have been acquired in this manner to give a new degree of stability to the entire bituminous industry. Normal requirements will be furnished by low-cost mines. The less efficient mines will be held in reserve to be called into production to supply peak periods of demand. In this connection authorities on coal point out that the bituminous industry in the past has taken little advantage of economies of large scale production. The consolidations now being effected, they say, will do much toward setting an example in such matters as improved organization under ground which is regarded by some as one of the weak spots in bituminous operation. Better co-ordination or effort under ground as well as the employment of more engineers and better talent all call for capital expenditures which large interests can undertake and which are

denied to those without such resources.

It is regarded as unthinkable that consolidations of bituminous mines could reach the point where any monopolistic control could be exercised. Even were a consolidation to take on a dominating character in a single district it would have to meet interdistrict competitor. There has been serious discussion of large consolidation among the producers of smokeless coal. Even were it possible to effect such a grouping the industry could do no more than get into the anthracite class but even then its product would be more vulnerable to inroads from substitutes.

Though it is doubted that any unselfish reason could be advanced by coal operators to the captive mine this trend within the industry does not present the same constructive possibilities as flow from consolidations. These mines restrict the market more than they restrict the output. Most of these properties produce for their owners only.

#### Buying Mines at Bargain Prices

Public utilities and the manufacturing interests are taking advantage of the existing situation, just as are the stronger coal companies, to buy mines at bargain prices. Here again the situation is clouded by uncertainty due to the fact that no central agency has the money with which to collect exact information. It is known, however, that the number of captive mines has increased greatly. The aggregate of their output is thought to be approaching two hundred million tons, more than one-third of the annual production. This tendency is believed to be having an appreciable effect on the price of coal.

Officials in Washington continue to emphasize their belief that the people of the northwest have cause for concern for their supply of winter fuel. Unless there is an immediate improvement in the Lake movement the chances greatly favor a serious situation should there be an early descent of winter. The solution of the situation lies entirely in the hands of the consumers as coal must be moved off the docks before additional supplies can be received.

In some official quarters there is a tendency to discount some of the optim-

#### Robbers Hide in Mine

Three desperadoes thought to be the three who robbed the Palisades, Colo., postoffice of \$15,000 on Aug. 2, hid in the mine of the Palisades Coal and Supply Co., with a posse hot on their trail and were still defending themselves in the mine on August 8. The siege of the working attracted the attention of the whole West. The mine was shut down, all openings at the surface were flood-lighted at nights and a heavily armed guard surrounded the place continuously. The posse even entered the mine frequently. But, although it thought they shot one of the three, no captures were made. The sheriff once prepared to gas the men out of the old mine but this plan was vetoed, and the guard stayed on the job while the town looked on.

ism which has been so rampant for the past two or three weeks. They point to the fact that the level of unfilled orders for steel is a particularly important barometer so far as coal is concerned. In May there was a 20 per cent decline in unfilled orders. In June there was a further decline of 20 per cent. In July the decline continued at a slightly less rate—15 per cent. There is reason to believe that August will show a much more favorable figure, but if the situation in the steel industry is indicative of the general trend coal operators are having a hard time figuring where enough demand will originate during the remainder of the year to affect their business materially.

#### May Reopen West Kentucky Mines with Wage Cut

Unconfirmed reports at Louisville, Ky., say that leading coal operators in western Kentucky plan to reopen mines Aug. 25, on a 1917 wage scale, 25 per cent below that effective when about 8,000 miners went on strike April 15. Union miners are not expected to accept the scale. W. G. Duncan, president of the Western Kentucky Coal Operators' Association says there is nothing to the rumor and added "the situation is delicate and any mention of the 1917 scale would make no end of trouble." Secretary George Baker refused to affirm or deny the report and Lonnie Jackson, president of District 23, United Mine Workers, said the Union officials had not been consulted on the move.

## State Insurance Will Continue Ten per Cent Below Company's Rates

The ten per cent differential of the State Workmen's Insurance Fund, which the insurance companies of Pennsylvania have been opposing since the fund was created in 1916, has been officially ratified by Governor Pinchot.

Samuel P. McColloch, State Insurance Commissioner, a year ago decided that the differential should be abolished, but he was overruled by Governor Pinchot and since then the companies have been endeavoring to get him to sustain the commissioner's views. The Governor said in a statement that the State fund is handicapped by being unable to pay commission to agents, that it must accept all risks and it can write only compensation insurance. The differential, he said, is an equalization which serves to balance in part certain disadvantages in cost of operation which weigh against the fund and not against the companies.

"At the time the State Workmen's Insurance Fund was established," the Governor said, "Many employees were not insured, thus leaving their workmen without sufficient protection. The fund was founded to make certain that every employer could, without fail, obtain insurance, and that his em-

ployees, in consequence, could be sure of the compensation to which they are entitled when accidents occur. When this administration took office there were still 50,000 employers in Pennsylvania who were not insured in either the State fund, in private companies or by self-insurance."

Most of the uninsured were small employers, many of them financially irresponsible, the Governor stated. Distress resulted because compensation due injured workmen or dependents could not be collected. There is little satisfaction, he said, to an injured workman to see his employer punished for not carrying insurance when he or his dependents are deprived of compensation properly due him under the law. In order to prevent such miscarriage of justice, eight states now provide compulsory workmen's insurance and require employers to take out insurance in the State insurance fund only. The Pennsylvania law provides for both State and private workmen's insurance.

"The State Fund is not an invasion by the State of the legitimate field of private business," said the Governor, "but a necessary welfare measure whose value to the working people of the State is beyond dispute." The statement declares that New York has a 15 per cent differential and Utah 20 per cent differential.

## Anthracite Plants Lay Off Awaiting Orders and Cars

Action by the Glen Alden Coal Co. in the week ending Aug. 9 in shutting down five of its collieries temporarily because of car shortages may prove to be the forerunner of a series of similar closings by anthracite operators throughout the northern anthracite region within the course of the next few weeks.

Though the shortage of cars was the immediate reason for the shut-down, the fundamental explanation lies in the slackness of the coal market at the present time. Thousands of cars of anthracite now ready for market remain on sidings and at docks throughout the country waiting for buyers, and while this condition continues there will be difficulty in obtaining "empties" for operation.

With most predictions for the future of the coal market anticipating a healthy revival in coal sales about the first of September, it is not expected

that the present situation will last long after the first of the month, and one local company, the Pennsylvania Coal Co., expressed the belief that it would be able to go through the period from now until Sept. 1 without any shut-downs. The Glen Alden Coal Co. announced its shut-down for a period "of two or three days only."

Reports from the lower anthracite region are to the effect that the Lehigh Valley Coal Co. is contemplating closing down several collieries, due to market conditions.

All the collieries of the Philadelphia & Reading Coal and Iron Co. in the Schuylkill and Northumberland regions were shut down the entire week. "The overstocked condition of the market," was given as the reason for the shut-down.

The chain of operations at Lattimer operated by Pardee Brothers and Co., Inc., suspended operations for the first half of the week. The reason for the suspension was explained by a statement from the company to the effect that repairs were being made.

## American Chemical Society To Discuss Coal Storage

Discussion of the nation's fuel supply will be a chief feature of the fall meeting of the American Chemical Society to be held at Cornell University, Sept. 8 to 13. Professor S. W. Parr, of the University of Illinois, will lead roundtable conferences on "The Storage of Coal and Spontaneous Combustion." Secretary Hoover's plans to relieve coal shortage and the report of the Coal Storage Committee of the American Engineering Council will be discussed.

The coal discussion will be held under the auspices of the Gas and Fuel Section, of which Dr. R. T. Haslam, of the Massachusetts Institute of Technology, is chairman. The Gas and Fuel Section will meet jointly with the Industrial and Engineering Division in a symposium on absorption. J. K. Davis, W. D. Langtry, N. R. Beagle, of Peoria, Ill., and W. H. Fulweiler, of Philadelphia, will participate in roundtable discussion on coal led by Professor Parr.

The tentative program also includes the following original papers: "Studies on Absorption of Naphthalene in Gas Oil," D. L. Kowalke; "The Rate of Flame Propagation and the Mass Law," F. W. Stevens; "Radiation from Non-Luminous Flames," W. G. Lovell, R. T. Haslam and R. D. Hunneman; "The Present Trend of the Manufactured Gas Industry," F. W. Steere; "Combustion Relations within the Fuel Bed of a Gas Producer," R. T. Haslam, F. T. Entwistle and W. E. Gladding; "Composition of the Volatile Matter Obtainable from Coke," H. J. Rose and G. G. Desy; "True Measurement of High Gas Temperature," R. T. Haslam, E. L. Chappell; "Studies on Spontaneous Combustion of Coal," J. D. Davis, John F. Byrne.

Foreign chemists will take part in the Ithaca meeting, among them Sir Robert Robertson, president of the Faraday Society; Sir Max Muspratt, one of the leading industrial chemists of Great Britain; and Prof. S. P. L. Sorensen of Copenhagen, a leader of the academic school, and internationally known for his work on the hydrogen ion.

## Kill Non-Union Miner With Bomb as He Enters Mine

A bomb was placed in a mine entry of the Hecla mine, of the St. Bernard division of the West Kentucky Coal Co., at Earlington, Ky., exploding when a switch was thrown to start current to a cutting machine, shortly before 8 a.m. Aug. 14, as a non-union crew was coming on the job. A colored mine worker was blown 30 ft. and instantly killed, and a driver was badly burned.

The explosion closely followed reports of Aug. 13 to the effect that mines in the section were to start non-union, Aug. 25. This is the first tragedy in the field since the strike was called on April 15. There are two airshafts close to the entry, and it is believed that the bomb was planted by entering through one of the airshafts. It is claimed that about 200 men are employed in the mine.

Clearfield Bituminous Coal Corporation's Tipple at Rossiter, Pa.

This structure, of concrete, steel and glass, is a good example of the practice, which has become general of recent years, of constructing all important mine buildings of permanent materials. Such buildings are so constructed today as to last throughout the estimated life of the mines they are intended to serve.

## Gates Explosion, Says Jury, Due to Accidental Ignition of Explosives

According to the report of the coroner's jury, the explosion at the Gates mine of the H. C. Frick Coke Co., July 25, which killed ten miners, was due to the accidental ignition of explosives used by the shotfirers, in No. 21 Room, Seventh Butt, North Section. The flame, says the jury, ignited coal dust suspended in the air.

The board of five mine inspectors, named by the state, was divided as to the origin of the blast. Two contended that a fall of rock set off the explosives which ignited the coal dust and the others believed the gas may have accumulated in the vicinity of Room 21 and been ignited by coal-cutting machines.

The inspectors' report closed with the following recommendations: 1—That the ventilation be arranged so as to reduce to a minimum, the chances of short circuiting the air current. 2—That proper examination be made and efficient supervision provided for the workings on the night shift. 3—That the Federal Bureau of Mines withhold its approval of electric detonators unless the type submitted for approval provides against their being exploded accidentally by electricity. 4—That greater care be exercised in the handling of detonators and explosives. 5—That all electric wires and equipment be installed and maintained and operated so as to reduce the danger of arcing to a minimum.

## Cumberland First-Aid Team Proves Best in Wyoming

A first-aid team from the Cumberland No. 2 mine of the Union Pacific Coal Co. won first prize at the Wyoming State First-Aid meet at Rock Springs, Wyo., Saturday, Aug. 9, with a score of 296 in a run-off with two other teams that had tied it at 293 for first place. Second place in the run-off went to the mine No. 4, Rock Springs team with a score of 294 and third to the team from Hanna, whose final score was 293. These three Union Pacific Coal Co. teams proved the best in the state. Fourth place went to a team from the Midwest Refining Co. from Casper, Wyo. It was this team's first venture in first-aid meets and W. D. Ryan, of the Bureau of Mines, who was master of ceremonies, complimented them highly. Also he said he had never seen better work in any first-aid meet in the country than was done by the various winners. The team that won first place was made up of these men: Capt. Lyman Fearn, T. H. Robinson, Jr., F. H. Buchanan, Charles Clark—substituting for Charles French who had been injured a few days before—and D. B. Ballantyne. The "patient" was Henry Goddard.

In the rescue contest which followed the first-aid meet, eight teams entered and No. 5 Mine of the Kemmerer Coal Co. which scored 175 won first place. Cumberland No. 1 and Hanna teams, both of the Union Pacific Coal Co., tied for second place with 165 and Cumberland won the cup on the toss of a coin.

## Ford Will Enter Retail Coal Business

W. B. Mayo, chief engineer, Ford Motor Co., when he arrived in Duluth on the Benson Ford, with 12,000 tons of bituminous coal aboard, the first Ford boat to enter the harbor, announced that coal sales offices would be opened by the company in Duluth and the Twin Cities. At first, probably, only carload shipments will be sold. The cargo of the Benson Ford will go to the Ford plants in St. Paul and Minneapolis, but when, later, all arrangements are made, Ford-mined coal may be carried over a Ford-railroad, the Detroit, Toledo and Ironton, be transported over the lakes in Ford boats, unloaded on a Ford dock (the Superior Coal & Dock Co.'s front just leased for one year by the Ford Motor Co.) and sold in Ford offices to the wholesale and retail trade, thus rescuing the Lake consumers from "the clutches of the coal profiteers." The D. T. & I., however, does not as yet tap Mr. Ford's eastern Kentucky fields.

## Three Mines to Be Shut Down Till Wage Contract Ends

B. M. Clark, president, Rochester & Pittsburgh Coal and Iron Co., has announced that Helvetia, Eleanor and Adrian will be closed down probably for two years, stating that with "an impossible wage scale" which makes the price of coal 50c. to \$1 less than the cost of production it is not feasible to operate these high-cost mines. Mr. Clark says: "We have reached the conclusion that the non-union fields can, and will, for several years to come, be able to furnish practically all the coal that the country demands and that the consumers will not pay us from 50c. to \$1 more per ton for coal than they can buy it for elsewhere. We expect to close not only the mines completely but the town also." The company has not yet decided whether to withdraw the pumps, but Mr. Clark stated that this probably will be done.

## Hudson's Bay Co. Entered Coal Business in 1852

An interesting part of the 1923 coal mining report of the Mines Department for British Columbia is the reproduction in facsimile of a letter dated Aug. 24, 1852, from James Douglas, then chief factor of the Hudson's Bay Co. in British Columbia, to Joseph McKay, a factor of the company, instructing him to proceed to Nanaimo (Nanaimo) Bay and to take possession "of the coal beds lately discovered there for and in behalf of the Hudson's Bay Co." and to levy a royalty on all coal mined there by anyone. This is the first authentic record of the commercial production of coal in this area.

The letter reads as follows:

"You will proceed with all possible diligence to Wentuhyusen Inlet, commonly known as Nanaimo Bay, and formally take possession of the coal beds lately discovered there for and in behalf of the Hudson's Bay Co.

"You will give due notice of that proceeding to the masters of all vessels arriving there and you will forbid all persons to work the coal either directly by means of their own labor or indirectly through indians or other parties employed for that purpose, except under the authority of a license from the Hudson's Bay Company.

"You will require from such persons as may be duly licensed to work coal by the Hudson's Bay Company security for the payment of a royalty of 2/6 a ton which you will levy on the spot upon all coal whether procured by mining or by purchase from the natives, the same to be held by you and from time to time to be duly accounted for.

"In the event of any breach or evasion of these regulations you will immediately take measures to communicate intelligence of the same to me."

## Italians Seek Coal Grant In Russian Field

An agreement soon to be concluded between Italy and Russia, according to the Mediterranean News Agency, will provide for the cession of a large section of the coal fields of the Donetz Basin to an Italo-Russian consortium for a number of years. By this agreement Italy hopes to be freed from dependence upon Great Britain, France and Belgium for her coal.

## First-Aid Team

Cumberland No. 2, Union Pacific Coal Co. won first prize at Wyoming State First-Aid Meet.

### Railroad to Nason Certified By Commerce Commission

The Interstate Commerce Commission has granted to the Jefferson Southwestern R.R. a certificate of public convenience and necessity to operate its line of railroad from Mount Vernon, Ill., to Nason, a new mining town, at which point is under development one of the largest coal mines in the world. It is owned by the Illinois Coal Corporation, with general offices in Chicago, of which Albert J. Nason is president.

The application for a certificate was granted by the Illinois Commerce Commission a year ago. It permitted this railroad to enter into intrastate business only. This case was hotly contested by some of the other carriers, but the Jefferson Southwestern R.R. finally won out through a Supreme Court decision, and although the interstate application was likewise opposed, the action of the Interstate Commerce Commission yesterday finally disposes of the matter.

### New Road Thoroughly Modern

This new railroad connects at Mount Vernon with the Chicago & Eastern Illinois, the Louisville & Nashville, the Southern, and W. C. & W. and it is proposed to continue the construction of this new road from the new town of Nason to a connection with the Chicago, Burlington & Quincy. At present the road is furnishing double daily passenger service in each direction between Mount Vernon and Nason by the use of a gasoline motor coach, which, in addition to the passengers it hauls, accommodates shipments of express and U. S. mail. The new road is modern in every respect; having been built of new 90-lb. steel and treated ties. It has no bridges, only two curves, and a maximum of 0.3 per cent grade. It is constructed to carry the heaviest locomotives.

The new town of Nason, which is approximately eleven miles southwest of the county seat of Jefferson County, Mount Vernon, has been laid out with considerable care by city planners and engineers who have provided ample space for parks, schools, churches, and other public buildings. Where a year

### Smokeless Coal Has Brisk Six Months of Operation

Total shipments of smokeless coal from southern West Virginia for the first six months of the current year aggregating 17,874,035 tons are 910,770 tons in excess of the first six months of 1923, according to a compilation made by the Winding Gulf Operators' Association.

ago was but a prairie is now a beautiful little city of over one thousand people, and it is expected that within the next three years this little town will have a population of over 5,000. The new mine is designed for a capacity of from twelve to fourteen thousand tons per day.

### Howat Runs for President of International Union

Alexander Howat, enfant terrible of District 14, United Mine Workers, is being dressed in his Sunday best for the international elections, the second Tuesday in December. Locals throughout the district already are sending in letters to the international board urging his nomination for international president.

Alex. isn't as popular with the neighbors as he is at home, however, and those who are pushing his campaign for the international presidency realize there is a good chance of his being declared ineligible by the board, before which he is on probation. Should the board take this action, time will remain to enter his name for the district presidency.

It was as president of District 14, a couple of years ago, that Howat, establishing a record for keeping his men on strike, got in bad not only with the Kansas state industrial court, but also with the international board. Only a few months ago the report came from Pittsburg, Kan., that he had gone back to work with pick and shovel in an effort to get reinstated in the union, and that one of the locals of the district had accepted his application for membership.

### Five Non-Union Miners Shot At Bull Hill, Oklahoma

War against the open shop mines of the Wilburton district in Oklahoma was renewed the night of Aug. 11, when five non-union miners, returning home from work in the Bull Hill mine, eighteen miles east of Wilburton, were shot from ambush and wounded severely. The attack took place on the eve of the preliminary hearing at Wilburton, of thirty-seven union miners accused of participating in the raid on the Kali-Inla mine near Cambria, Okla., last month. And it followed by only a few days the shooting from ambush of a non-union miner, fishing near the scene of the attack of Aug. 11.

The five men were the first of the day shift to quit the mine. They were followed closely by their comrades, who reached them, however, too late either to protect them or to catch their assailants. The Bull Hill mine employs fifty men. It is owned by J. B. Hilling, Ray Morgan and W. B. Merchant, of Red Oak, Okla. It has been operating as a non-union mine several weeks.

### Canada Delays Shock Attack On United States Coal

At a conference held at Edmonton, Alta., between Premier Greenfield, Hon. Charles Stewart, Dominion Minister of the Interior, and Sir Henry Thornton, President of the Canadian National Railways, it was decided that the projected experimental shipments of Alberta coal to Eastern Canada would not be undertaken this year, owing to lack of time to make the necessary arrangements.

The Premier pointed out that he had had no information from Ottawa as to any arrangement for putting into effect the contemplated plan of federal aid, and that until the Dominion authorities took action in that direction nothing could be done. Hon. Mr. Stewart said that assistance from the Dominion Government would be conditional upon the operators reducing their prices on the coal going East as they must be willing to co-operate with the Government by cutting prices at the mine if the Government is to help to pay the cost of transportation.

## "Niggerheads" in Utah Coal Are Dinosaurs' Tracks

An article appearing in the current issue of *Natural History*, written by Prof. William Peterson, director and geologist of the agricultural experiment station of the Utah Agricultural College, describes and accounts for the tracks of prehistoric dinosaurs in the roofs of Utah coal mines.

Professor Peterson says, in part:

"To view the tracks of ancient cretaceous monsters is not an entirely new experience, but to view these tracks from beneath instead of from above is somewhat of a novelty. This is a privilege open to those interested in the ancient life of the cretaceous seas of Utah and Colorado. It was the writer's good fortune to spend three summers in a detailed survey and inspection of the coal deposits of Utah. While he was examining the underground workings of many of the mines, attention was called to certain protuberances from the coal-seam roof. A definite shape had been recognized in the case of some of these, though most of them were spoken of as "carbuncles," "niggerheads," and under similar terms. In areas where the coal was low these protuberances had to be removed to give room for the mine hauling, for some of them projected as much as a foot below the roof of the coal seam. In some places the projections appear in groups while in others they are solitary.

"After inspecting hundreds of these protuberances, the writer agrees with some of the mine foremen and superintendents that these peculiar formations undoubtedly had their origin as tracks of ancient monsters which tramped through or around the border of the cretaceous seas. The tracks seem to have been made at a time when the peat accumulation was covered with a foot or more of mud. The layer of mud was not sufficiently thick to support the weight of the animal walking over it. The feet sank through the mud several inches or even more than a foot at times, into the soft yielding peat underneath. Some mud was pushed into the peat as the animal brought down its weight, and as it drew out its foot the footprint would be filled with mud from above.

### Peat Changed to Coal

"As time went on, nature's distillation reduced the peat to coal, and the mud with its track projections was converted into solid rock. In most places the coal is easily separated from the roof, leaving the track-shaped protuberance extending partly or wholly as a definite appendage from the ceiling. When the coal is completely removed, the tracks appear in various forms. In some cases the footprints project only part way through the roof and in others they project so far that a clear space is shown between the portion of the track represented by the toes and the solid roof. It is interesting to note that, as far as observed, the largest tracks are the ones which protrude farthest from the rock roof. The material filling the track varies slightly, but is for the most part an arenaceous shale or argillaceous sandstone.

"The animals seem to have walked for the most part along trails or definite paths. It was noted that some of these paths are 20 or 30 ft. in width, and the exposures in many entries and rooms of the coal mines show them to be comparatively straight in alignment. The individual tracks in the paths are seldom clearly outlined, and only when one of the animals has traveled independently does every imprint become distinct. In several places it has happened that an entry of the coal mine has followed approximately the path of a single animal, thus exposing several of the tracks for measurement and comparison. Seven consecutive tracks are shown in the old Ballard mine on the property of the American Fuel Co., located on the Denver & Rio Grande R.R. about eight miles north of Thompson Springs. These tracks are among the largest observed.

"In a different entry of the mine, tracks of similar size are found, and by courtesy of the company one of these was taken down and shipped to the geological museum of the Utah Agricultural College at Logan. The track measures 31 in. between the spread of the outer toes and 32 in. from the heel to the front of the middle toe. Near the point of separation the toes are from 6 to 8 in. in diameter, and the toes are so pointed as to indicate the presence of rather sharp claws on the end of each toe."

## Kentucky Insurance Company Fails to Pay Compensation

C. C. Ousley, secretary of the Associated Industries of Kentucky, in a bulletin issued today, makes a strong appeal for safe insurance, in a comment under the heading: "Employer Left to Hold the Bag." He said:

More than one employer probably experienced an unpleasant sensation on reading a recent newspaper dispatch telling how a judge of the Court of Appeals has refused to restrain the sheriff of an eastern Kentucky county from executing judgment against a coal company on an award of the Kentucky Workmen's Compensation Board in favor of an injured employee. The facts as stated in the press, were that the company had insured its liability with a carrier which was doing business in the State in the spring of 1922, when the accident occurred, and which, it is claimed, at the time stood approved by the Workmen's Compensation Board. The carriers' license was not renewed the following July, and about a year later the insurance company went out of business. He adds:

"If the facts are as reported in the press, improved administration is one of the things which would bring greater comfort to the mind of the insuring employer. Not only close supervision of carriers while they are in this field is desirable, but assurance that on retirement they are leaving behind deposits adequately protecting their former clients. This is essential to assure the employer a good night's rest where he has workers with allowed claims. Care in the selection of a carrier is of course something the employer himself can exercise with profit."

## Gutheim Opposes a Rehearing Of Northwest Freight Case

Reply to the reasons advanced for a rehearing in the case of the Northwestern Coal Dock Operators' Association versus the Chicago & Alton Railroad Co. has been made by August G. Gutheim on behalf of the C. Reiss Coal Co. and the Milwaukee Western Fuel Co. In opposing the rehearing, Mr. Gutheim points out that the Interstate Commerce Commission and other government organizations in forcing, protecting and pooling the movement of coal to these docks indicates that the docks constitute a necessity for the fueling of the Northwest. "This admitted," he says, "it hardly could be argued seriously that they were entitled to do business only at such times as other producers could not take care of all northwestern needs. If that be the rule, then the docks, with their enormous investment in facilities and in coal, are ruined."

He cites figures to show that "the tonnage from southern Illinois has increased in greater proportion than that from the docks." He refers to the inference on the part of southern Illinois carriers to the effect that southern Illinois rates were exceptionally low. Mr. Gutheim further contends that the commission is amply empowered to make the orders which have been attacked by the Illinois Coal Traffic Bureau and the Wisconsin Traffic Association. At another point in his brief, Mr. Gutheim makes this important statement:

### Shippers Entitled to Protection

"All these petitioners seem to overlook the fact that not only the consumers, but the shippers, whether docks or mines and the carriers are entitled to the protection of the law. The complainants for whom this answer is filed, did not begin this litigation. Certainly they never started out with the sole purpose in mind of making consumers pay more for coal. But as has already been noted, they were compelled, as a matter of defense to the complaint originally filed by the Illinois interests, to file a complaint bringing in issue the rates from southern Illinois—the real shipping rates, which were carefully left out of the picture by the Illinois complainants. It is only as a result of this that there have finally come the orders of the commission under attack.

### Say Rates Should Not Be Changed

"The docks were compelled as a matter of defense to raise before the commission the lawfulness of the adjustment between themselves and southern Illinois in reaching Wisconsin destinations. The petitioners stress the fact that this is no time to increase rates. The fact remains that the docks in adopting their plan of defense against the attack of Illinois were under the necessity of recognizing that this commission might consider the present no time to reduce any of the rates here involved. The question being originally raised by Illinois, and the unlawful preference and prejudice being found to exist, the commission has done the only thing permitted by the law in ordering its removal."

# Roof, Ribs and Floor Wetted by This Sprinkler Car

By FRED SCAMMEL  
War, W. Va.

**E**XPLOSIONS resulting from accumulations of coal dust within the mines, have caused many mining companies to seek means for allaying such dust. The Warriar Coal Co., at War, W. Va., has given serious consideration to this problem, with the result that the sprinkler car shown in the accompanying illustration has been developed and put into use.

In operation this car is pushed along the track ahead of a locomotive. Inasmuch as the water is projected forward in a cone-shaped spray the men operating the machine are always kept dry, even though all surfaces of the rooms, headings and other passages where this machine is used are thoroughly and impartially wetted down.

This machine sprinkles floor, roof and ribs alike, only two men being required for its operation, and the entire mine may be treated by it in from 4 to 5 hr. Thus far highly satisfactory results have been secured by its use. Its operation has been endorsed by the district mine inspector.

This sprinkler consists of a tank of 1,000 gal. capacity mounted on a mine-car truck. On the rear end of this truck is placed a 3-hp. motor which is

back-gearred to a shaft extending through the tank. On the forward end of this shaft, which is fitted with stuffing boxes where it passes through the tank walls, a sprinkler wheel is mounted. This is fed with water from the tank through a 2-in. pipe.

Probably the most unusual feature of this machine is the sprinkler wheel. This somewhat resembles the impeller of a centrifugal pump, consisting essentially of two disks, cupped in opposite directions, with vanes between them. The rear disk overlaps the forward one so that the water issuing from between them is directed forward by it. Water is thus projected from the wheel in a cone-shaped spray.

Ribs, roof and roadway are thus sprinkled, the machine throwing water onto the entire perimeter of the passage within which it operates. Furthermore the sprinkler will thoroughly wet down the face of a room even though the track may not extend entirely to the face. The bug dust and other fine coal in the room is thus wetted down and may be loaded out without the danger of its flying about which is always present when such material is loaded dry.

Sprinkler Car and Some of Its Details

The sprinkler head or wheel, which is operated by a motor on the rear of the car, both in appearance and effect somewhat resembles the impeller of a centrifugal pump. Inasmuch as the rear disk is cupped forward and overlaps the front disk, water is thrown ahead of the car in a cone-shaped spray, thoroughly wetting all surfaces of the mine passage while the men operating the car are kept dry.

## An Uncleaned Shothole May Cause a Misfire

By GEORGE EVANS  
Technical Representative E. I. du Pont  
de Nemours

Coal dust in boreholes affects the proper detonation of ammonia permissible dynamites. Where jackhammers are used, a  $\frac{3}{4}$  to 1-in. gas pipe is connected to the air line and then pushed into the borehole two or three times, so as to blow out the dust. This procedure will not clean the holes completely especially if they are from 6 to 9 ft. long. Enough dust remains so that when the dynamite cartridges are loaded a certain quantity of it will lodge between the cartridges. The results of allowing coal dust to interpose itself between cartridges of ammonia permissibles can be seen readily from the following tests, which were made by placing a certain quantity of coal dust between two 1 $\frac{1}{2}$ x8-in. cartridges of permissible powder. No tamping was used and the charges were unconfined.

### Tests of Detonation of One Cartridge by Another with Explosive Unconfined

Thickness of Coal Dust Between Cartridges, Inches	Number of Tests Made	Failures to Detonate Second Cartridge
$\frac{1}{8}$	5	0
$\frac{1}{4}$	5	0
$\frac{1}{2}$	5	5

It will be noted that 1 in. of coal dust sufficed to prevent the detonation of one cartridge by another.

Additional tests were made to determine what results would be obtained if certain quantities of coal dust were placed between two 1 $\frac{1}{2}$ x8-in. cartridges of permissible explosives loaded in a borehole, but in this case with the charges well confined by tamping. Much better results were obtained as indicated below:

### Test of Detonation of One Cartridge by Another with Explosive Confined

Thickness of Coal Dust Between Cartridges, Inches	Number of Tests Made	Detonations of Second Cartridge	Failures of Second Cartridge
2	5	5	0
3	2	1	1
4	2	1	1

6	2	1	1

It will be noted that the confined charge did not fail until 2 in. more of coal dust had been introduced than was the case with unconfined charges. This again proves that tamping boreholes full to the collar is necessary to obtain satisfactory results from these ammonia permissibles.

## Practical Pointers For Electrical And Mechanical Men

### How Repair Costs Have Been Reduced By a Large Coal Company

By Knowing How Electrical Apparatus Is Constructed Better Care Is Taken—Meters and Instruments Are Periodically Tested and Checked

AT THE main office of the Pennsylvania Coal & Coke Co., Cresson, Pa., every possible means has been provided to familiarize the workmen with electricity. The rapid expansion of the various uses of electrical energy has made it almost impossible for even those directly working with it to study its many applications.

Workmen at the mines use electrical equipment as tools to assist them in their labors. To them electricity is usually an unknown science. Nevertheless, these men must learn to operate the new machinery and so must learn something about the mysterious power by which it is driven.

Hazards and accidents are always frequent when a man does not understand his work or the equipment he uses. A repair man who must keep the electrical apparatus in good condition can do his work much better if his knowledge of electricity is not limited to a few elementary ideas of the subject.

To tell a workman or mine foreman that he must not overload his machines does not carry any convincing evidence of the damage that

trate the ratios of three-phase and single-phase voltages and currents.

From the test board shown in Fig. 1, single-, two-, three- or six-phase alternating-current voltages are obtainable. This panel is located at A in the large picture and is protected against short-circuits, overloads, and other dangers. The other illustra-

Fig. 2. Classroom and Laboratory Combined at Pennsylvania Coal & Coke Co.'s Cresson Office

This is where the workmen gather to study the machines they work with. At the board A both alternating and direct current are available for tests. Demonstrations are carried on here to show how different machines and parts function.

may result. Oftentimes the men do not know when they are endangering themselves or others or damaging apparatus. It was with these points in mind that J. F. MacWilliams, the electrical engineer of the company, started, in the room shown in the large illustration, a school of instruction for his men and other workmen at the mines who are responsible for the use of electrical equipment.

This room is equipped with an alternating-current circuit from which, by the use of transformers and a motor-generator set, it is possible to obtain any desired alternating- or direct-current voltage.

Every Thursday evening is held a class in practical electricity. Machinery commonly used around the mines is studied, taken apart and tested. The important features of the apparatus are described and its function and limitations are considered.

Recently the class finished the construction of a rotary converter made from a 15-hp. crane motor. This machine was built and tested to illus-

tion, Fig. 3, shows some of the testing meters used in the school. In the center of the group is a new bond testing instrument developed by Mr. MacWilliams. Aside from being used

Fig. 3. Group of Testing Instruments

These meters make it possible to test almost any piece of electrical equipment while in operation. These instruments are also part of the metering apparatus used by the company.

as a classroom, periodic tests and inspection of electric meters, instruments, etc., are made here. In a separate room nearby, spare repair parts and emergency equipment are kept.

Fig. 1. Alternating-Current Test Board

By changing the connections on this board many different voltages are obtainable for testing purposes. Single-, two-, three- and six-phase circuits can be taken from the panel.

By using the room for these different purposes the cost of the equipment is not directly charged against the school; in fact, the use of the room by the class is after working hours. Many novel and interesting devices have been worked out in this little laboratory, and the reduced maintenance costs at the mines have amply repaid the management for the investment necessary for training the men in the care of electrical machinery.

### Slitting Chisel You Can Make for Yourself

The mechanical man at the coal mines often has need for special tools that cannot be purchased at any store or supply house and which, consequently, must be made on the job. One such implement known as a slitting chisel is shown in the accompanying sketch. Although this is an extremely

Tube-Slitting Chisel

useful instrument for slitting tubes, shearing plates and the like, and although there is nothing particularly new about it, yet it can seldom, if ever, be found for sale in the ordinary hardware or tool store.

For tube cutting, as in removing a tube from a boiler, the blade should be slightly longer than the diameter of the tube. As may be seen this blade is relieved throughout its length to prevent its binding in the incision made. The edge or point is square, that is, the cutting done is a shearing action on the square corner of the blade point. In cutting off a tube one corner of the point is first driven through the tube wall and then a strip cut out entirely around the tube.

Projector Lamps Light This Mine Yard

These units are placed so as to reflect the light over wide areas thus providing good lighting for all important sections. On dark winter days the output of these mines will not be lowered due to lack of light.

### Floodlighting the Mine Yard

Oftentimes it is difficult to light certain regions around the mine yard. Ordinary lamps with flat reflectors cannot be located where the light is most needed. Poles or posts promiscuously placed are often in the way when changes are being made. Breakage, theft and loss is most frequent when lamps may be easily reached. Perhaps most serious of all is the dust and dirt which usually sticks to the open lamp and reflector and seriously cuts down the light.

At the No. 15 Mine of the Consolidated Coal Co., near Staunton, Ill., most of the outside mine lighting is done by floodlight lamps installed on permanent structures in the yard. These lights project a wide cone of light which illuminates a large area. Because the lamps and reflectors are enclosed the quantity of light furnished does not

vary. What little dirt gets on the glass cover of the unit is easily washed off by the rain or removed by occasional cleaning by one of the workmen.

### One Way to Keep the Yard Safe and Clean

It is rather unusual to visit a mine and not find it necessary to walk through carbide dust. At Thermal

Where Carbide Lamps are Emptied

By providing receptacles like these the fumes of carbide are not spread all around the mine yard.

Mine No. 4 of the Donk Bros. Coal and Coke Co., near Edwardsville, Ill., artistically designed boxes set up on small poles are located where the miner can empty his carbide lamp when he leaves the mine.

Careless throwing of carbide around the mine yard often causes accidents to say nothing of the obnoxious smell that arises from the dust whenever it rains or snows.

Pumping Unit Works Whenever Water Enters the Sump

This unit consists of a motor and a pump, the latter having geared parts which, without priming trap the water or air inside the pump casing and discharge it. The pump operates continuously and keeps its sump nearly empty at all times. Owing to the simplicity of its construction the pump requires little attention.

## Discussion

### Three Suggestions to Methods of Mining a Difficult Coal Seam

#### Best Plan Probably Is to Use a High-Cutting Machine to Cut Out the Rash Above the Bottom Seam

In the problem which a West Virginia operator propounds on page 22 of this volume I assume that the 10 in. of drawslate is loose enough that it will fall when the coal is shot down and that the roof above the drawslate is a good hard stratum that can be held in place. The seam could be worked by what is known as the double-entry or double-stall system. In this system the room is driven usually 40 ft. wide where there is a good top and bottom. This makes it possible to use two tracks for loading out the coal, and to build all refuse into walls or to stow it in the gob between the tracks. The tracks on each side of the room should be kept 4 ft. clear of the room ribs. This allows posts to be set along the side between the track and the rib side of the coal. A row of posts is set also along the other side of each track. The posts usually set in the gob should also be used in this instance. The drawslate could be used to form a building along the gob side of the track.

Two methods of extraction could be used successfully. The coal-cutting machine could be set on the top of the bottom or 11-in. seam of coal, allowing the machine to make its cut in the 5½ in. of mixed slate and coal. Then, perhaps, the 4½-in. seam of coal and the 4½ in. slate parting might fall as the machine is undercutting it. If not it could be taken down by an experienced man. He

might have to put in a few light shots to dislodge it, but that operation would not be laborious enough to prevent the work being done at a reasonable figure.

Fig. 2—Rubbish in Seam Is Partly Cut Out and Partly Removed by Powder or Bar. Upper and Lower Benches Are Then Loaded

Of course more room must be left than is shown between gob and coal face and where an ordinary low-cutting mining machine is used, the lower bench must be left 6 ft. behind the face of the upper bench.

The cuts thus enlarged could be shoveled out into the gob and stowed there, thereby leaving the top coal whole. This would uncover the bottom coal so that it could be removed later and at the same time it would free the main seam.

However, the machine cut might be

difficult to lift. This would expose the 11-in. seam which could be mined somewhat later. I am assuming, of course, that the 11-in. seam is good coal.

In my opinion the latter scheme is the better, even if it should cost a few cents more to lift the 4½ in. of coal and the 5½ in. of rash. If a 6-ft. cut was made by the cutting machine it should not be difficult to remove the underlying 9½ in. Of course, if this method were adopted, the miners would have to take due precautions while removing the refuse. The coal would have to be supported by sprags as shown in the illustration.

As the top coal is hard, a good shot in each corner and a number of light shots across the face would bring down the face if the sprags were redrawn. Another suggestion is to get a machine that would stand on the hard sandstone bottom and cut in either the soft slate or the rash as has been outlined. I understand that there are a number of machines in the market that will cut at a level 12-in. or more above the floor. By using such a machine the bottom coal could be kept up with the main seam and a good bottom on which the machine would travel freely would be available. This would be better for timbering and loading. In the first two plants the bottom coal would have to be left at least 6 ft. back of the main coal face in order to give the machine a berm on which to travel. The last suggestion would appear to be the best.

Newcastle, Wash.

JAMES GRAY.

Fig. 1—Double Entry Room with Two Tracks and Gob Between

Posts are put on either side of track to give firm support to roof. Drawslate, soft slate, rash and thin bed of coal will more than fill gob.

# Production And the Market

## Lack of Funds of Manufacturers and Householders Restricts Sales, but Soft-Coal Prices Improve

In the Middle West the bituminous-coal industry seems to be experiencing a slight improvement, but in the East, especially in New England, the report is quite discouraging. The public appears to be delaying buying not only from a sense that coal will be available when demanded but because business has been so poor that money is not obtainable for the making of purchases, even where the consumer has a conviction that there will be a scarcity this winter and that it would be well for him to get under cover. The cry seems general that purchasers are slow to pay. But in the Northwest, where the farmer is looking for and actually experiencing prosperity and the ore mines are preparing for resumption, the coal is not being taken from the docks so that more can be brought in. There is need for greater circumspection in that region, for the indications are that the wherewithal to purchase coal is not lacking.

### Spot-Price Index Advances

Coal Age Index of spot prices of bituminous coal shows an increase during the past week, standing on Aug. 18 at 165, the corresponding price being \$2.00, as against 163 and \$1.98 the previous week.

Hampton Roads dumpings for all accounts during the week ended Aug. 13 totaled 395,568 net tons, an increase of 36,652 tons from the week preceding.

A sharp upturn marked the movement of coal at the lakes, dumpings during the week ended Aug. 17, according to the Ore & Coal Exchange, being as follows: For cargo, 765,872 net tons; for fuel, 42,785 net tons, compared with 725,168 and 47,054 net tons respectively during the preceding week.

The production of bituminous coal for the week ending Aug. 9 increased slightly, the output according to

the Geological Survey, totaling 7,800,000 net tons. The previous week showed an output of 7,484,000 tons according to revised figures. Anthracite production decreased, being 1,683,000 net tons in the week ending Aug. 9 and 1,720,000 tons in the previous week.

### Hard-Coal Market Depressed

Anthracite is even more loggy than bituminous coal though stove size seems to be in great demand. However, if there were a big supply that demand would soon evaporate. Unless the anthracite companies have a similar demand for other sizes they are unable to comply with the insistent demand for stove, which in economical operation can represent only a certain por-

tion of the whole production. The purchase of anthracite seems to be delayed by the lower earning ability of the consumer. He finds all his dollars expended for immediate needs and does not look to the future. If he does not buy soon, however, the retailers will be doling out anthracite in single-ton lots and the snowbirds with their poor coal will come back, eventualities good neither for public, operator nor retailer.

### Estimates of Production

	(Net Tons)	
<b>BITUMINOUS</b>		
	1923	1924

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

## No Change in Midwest Market

Domestic buying continues slow in the Midwest, although there is some improvement in southern Illinois high grade. The cheaper coals seem to be at a standstill. Anthracite and smokeless are slow, but coke shows a little activity. Wagonload steam is not a factor, and carload and country steam are sluggish. Domestic business for certain grades of coal in the country shows up well in spots. This forecasts good conditions a little later.

In the Carterville, Duquoin, Mount Olive and Standard fields the situation is unchanged. In the Carterville and Duquoin fields the mines are working one or two days a week with a mine here and there doing better. In these latter fields and in the Standard all sizes remain unbilled on track. The Mt. Olive moves a little railroad tonnage, but little domestic coal is sold, and the steam tonnage just about keeps up with contract requirements. In the Standard field some mines are closing and some starting. Lump movement to the Northwestern territory has improved a little and screenings have been in demand for a day or two. Strip mines are making headway. Tonnages are increasing and the mines run steadily with prices 25c.@50c. below

those of shaft mines. They are loading some railroad coal.

A much better tone prevailed in the Chicago coal market this week. Orders were booked in satisfactory volume and many promising inquiries were received. For the first time in weeks the holding tracks in the Chicago switching districts were free from distress coal and for the first time this year substantial contracts were closed. High-grade domestic lump, egg and nut, especially the first two mentioned, are moving in some volume to the Northwest. The country retailers in Illinois and Indiana are still holding back. West Virginia and Kentucky splints are being shipped in large quantities and the quantity will increase if the proposed through rates go into effect this fall.

There is no change in the St. Louis situation, although a little domestic business has begun to move through the dealers, mostly for middle-grade coals. Anthracite, smokeless and coke are moving slow and for standard there is no demand at all. A little wagonload steam is moving and orders for carload steam are hard to find. Country domestic is picking up and this improvement is quite noticeable. Country steam, however, is slow and there is nothing of any consequence moving out to Chicago or the Northwestern steam markets.

Index .....	1924			1923
	Aug. 18	Aug. 11	Aug. 4	Aug. 20
Weighted average price .....	165	163	163	197
	\$2.00	\$1.98	\$1.98	\$2.38

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Louisville Breathes More Easily

The feeling in Louisville is much better than it has been, for the fall demand for prepared sizes is developing, with much better general demand scattered over various sections of the country. Eastern Kentucky operators are busier than they have been, and have fewer cars of unsold coal on track. Some of them claim that except for the industrial demand for screenings the price would have been reduced and prices of prepared coal correspondingly increased. Indications are that there will be advances of 25@50c. a ton on prepared sizes by the end of the month, or early in September, regardless of the screenings market, which will break if prepared demand improves.

Demand in the western Kentucky producing sections is improving somewhat on scattered orders from various sections for prepared sizes, while increased industrial activity is taking care of present production of screenings, which is a shade higher than they have been and in good demand. As a result of better demand and better operating time, and with about half the field still strike bound, there is an upward tendency in the price quoted.

Northwest Growing More Hopeful

Trade in Duluth generally is stronger, although Kentucky run-of-pile was reduced to \$5.50 from \$5.75. Forty-three cargoes arrived this week of which eleven were anthracite. There will be probably plenty of hard coal in the Northwest this year to meet requirements. Twenty-two cargoes are reported on the way from lower lake ports and of these five are hard coal.

The anthracite market seems to be starting, the weather being unseasonably cold. Inquiry is better in bituminous. The iron mines are preparing to start operations.

Prices on soft coal in the Twin Cities remain about as they have been for some time. So southern Illinois coal has been on the basis of \$2.75@3 for some time. Dock prices are unchanged.

The volume of business in the Milwaukee coal market continues unchanged. The slight spurt in buying, heretofore noted, has subsided and business is quiet with buyers showing a total lack of interest both in city and country. Lake receipts are slow. Thus far cargo receipts of anthracite aggregate 412,488 tons and of soft coal 1,519,893 tons. This represents a falling off of 20 per cent in the former and about 33 per cent in the latter compared with last year's receipts up to this time.

Business is slow to pick up in the Southwest. Prices are unchanged from last week. Arkansas semi-anthracite is \$5.50 to \$7 for lump; \$3.50 for mine run and \$2 for screenings. Henryetta, Okla., lump is \$4.50; nut, \$4; mine run, \$3.25 to \$3.50 and screenings, \$2.

The market in Colorado shows little, if any, change from last week. Though a number of inquiries have been received coal sales are still slow with dealers buying only that for which they have immediate need. The mines averaged twenty hours last week with 48 per cent of the working time lost on account of lack of market. Prices are unchanged.

In Utah the mines are working about three days a week. Prices are unsettled. Only domestic lump is moving satisfactorily. The metal-mining industry is providing a fair market for coal. The sugar factories are taking some slack and the railroads are buying a little more coal than they were, but both the latter markets are poor. The Central Western Regional Advisory Board has passed a resolution urging all consumers to buy their supplies now.

Cincinnati Just a Little Happier

Prices have changed a little in Cincinnati during the past week, and the undertone is firmer, for consumers are now disposed to buy.

Bituminous coal for domestic use is passing in greater volume to the Northwest and the minimum price for steam slack has increased owing to a decreased production of block and 4-in. lump. Run-of-mine also is a bit stronger. Egg and 2-in., the favorite lake sizes, are the only makes that have failed to show a definite price change.

With a slightly better feeling in domestic coal circles the Columbus coal trade continues to show a better tone. Dealer buying is now the best feature. Some retailers still have good stocks, but others are almost to rock bottom and are coming into the market. City dealers are having a better trade but hardly up to normal for the time of year. Householders are showing preference for smokeless, splints and Kentucky varieties, although a fair quantity of southern Ohio coal is moving. Demand for steam tonnage shows no material improvement. Slack is plentiful and prices weak, although there is now less demurrage coal on the local market. Production shows only slight increases. In the Hocking Valley and Pomeroy fields the output is about 15 per cent of capacity. Lake trade is showing signs of a let-up owing to congestion at some of the lower lake ports.

Pittsburgh Slowly Recovers

In the last two months there has been a noticeable increase in production in the Pittsburgh district, but this has represented increased business between operators and their regular customers rather than heavier sales in the open market. The former business replaces the usual contracts for the coal year and is subject to periodic adjustments. For the Pittsburgh district steam mine-run these have averaged close to \$1.90 right along. Some business is done probably at \$2, but little if any as low as \$1.75, that being a price reached in the spot market frequently by small operators who have no regular trade and often sell through dealers. Some coal has been shipped in the lake trade but for affiliated interests.

Some Connellsville operators are trying to sell steam coal, coal that, running above the sulphur limit for coking, is otherwise good in analysis, but soft. This often sells at \$1.50 and sometimes at \$1.40. Connellsville Sewickley, better in structure but not in analysis, sells as low as \$1.10.

Operators and jobbers report that in general the demand for steam fuel in eastern Ohio shows an improved tone with inquiries more numerous and more odd-lot buying. Some industrial contracts have been made during the past few weeks covering fuel requirements up to March 31 next. Domestic trade also is improving. Retail yards are more active. The strongest demand and weakest supply in the steam trade is for slack and nut and slack, which accounts for a stiffening in prices on these grades.

Some shippers to the Buffalo market, mostly near producing centers, are asking a little more for their coal, but Buffalo shippers decline to pay it. Bituminous prices remain unsteady at \$2.25@2.50 for Youghiogheny gas lump, \$2@2.25 for Pittsburgh and No. 8 steam lump, \$1.50@1.75 for all mine run and \$1.10@1.25 for slack.

### New England Not at All Cheerful

The slightly firmer price tendency in tidewater coal at Boston, noted in last week's issue, has entirely disappeared so that \$5.40 gross ton on cars, Boston, has been the going figure for New River and Pocahontas. It is reliably reported that one shipper has offered good quality coal at \$5.25 on cars if a large tonnage is purchased. The offering of a cargo of nut and slack at about \$5.25 on cars Boston made buyers surmise that there had been further break in mine-run prices and buying slowed considerably. For mine-run coal, \$5.40 on cars, Providence, is as low as is known to have been named this week, but \$5.50 has been obtained not infrequently and a little tonnage actually brought \$5.60. Some, not Pool No. 1, has been offered at \$5.25 on cars, Providence.

The southern loading ports have shipped quite freely the past week and stocks are large at privately owned docks. High-grade low-volatile coal is reported as offered at \$4 gross ton, f.o.b. Hampton Roads, but local shippers have been unable to pick up quality coal in cargo lots at less than \$4.10 and \$4.20 has been paid. This does not mean, however, that no \$4 coal has been shipped to New England.

The all-rail bituminous market remains dull though a little more active in the past week. A few small lots of choice steam coal have sold at \$2.90 net ton, mines, in the face of offerings of certain Pool No. 1 at \$2.35.

Coastwise vessel freights are firming noticeably, 80@85c. now being demanded for steamers of about 5,000 tons, Hampton Roads to Boston, against 70c. a few weeks ago. For this size of boat to Providence 75c. has been refused the past week and 80c. demanded. The larger tonnage craft—7,500 tons—can be chartered to Boston at 65c.

### More Inquiries in Atlantic Coast Markets

In the soft-coal market of New York there is no change of consequence, but an increased number of inquiries have been received. It is thought that the trade has passed through the worst of the depression. A feature of the local market in an unfavorable way is the low rate of freight being quoted from Hampton Roads. It has the effect of curtailing still more the market for Pennsylvania coal.

No one can get enthusiastic about the improvement in the Philadelphia market, as the tonnage moved is still light, though increasing. The smaller users, who ask for prices about this time of the year, are making inquiries and buying a few cars. There is still much conflicting opinion as to business conditions. Railroads are only taking their normal supply of fuel, with no disposition to stock-up. Prices are unchanged.

Baltimore soft-coal jobbers and operating interests admit freely that they cannot point to any specific improvement in the situation there or at the mines. Nevertheless a decidedly more optimistic feeling is exhibited in local offices, probably because inquiries are beginning to drift in slowly from industries which have been either closed or operating on a part time schedule for some time past. Demand is poor.

### Public Not Buying Anthracite

During the past week the anthracite market in New York has slowed down even more than before. Even stove coal is in less active demand. It is thought that the unusually warm spell may have had an effect upon the retail trade, that was reflected in the wholesale market after the lapse of a few days. Stove is the only coal selling above the company circular, and even that is dragging a bit now.

Philadelphia records a faint indication of betterment in the retailing of hard coal. The big producers for the third week are running on a four-day schedule, and but few of the independents have been able to avoid short time.

The retailer is disposed to fill all vacant spaces with nut coal. Experience tells him that it will be well to have it on hand long before the first of the year. Prices at the mines are stabilized, and none of the more responsible concerns show any indication of shading them. The demand for stove does not waver, but as most of the buying is for the winter, the dealers are content to wait their turn for it. Pea and egg are still a bit quiet. The big mining companies are not storing prepared sizes this year so the public cannot draw from that source in the winter. Steam coals are still dull, barley being in best demand.

The hard-coal purchasing public of Baltimore remains largely unresponsive to the appeals of anthracite coal dealers to place their orders quickly. Coal retailers have declared without result that there will probably be another 25c. per ton advance in prices on Sept. 1.

In Buffalo the anthracite trade is slow as ever, many people not earning enough to pay for their winter's supply. In New England the market is good for stove anthracite at \$9.20, but other sizes are not wanted. Egg and nut are \$8.25. Pea and steam sizes are practically unsalable at any figure.

Spot furnace coke is still firm at \$3. There is no distress tonnage. Consumption is believed to have stopped decreasing. No additional furnaces seem likely to go out, but no furnaces are likely to be lighted. An eastern furnace, covered to Oct. 1, has been sounding the market on fourth-quarter contract, and finds the \$3.25 price quoted firmly, but holds out for \$3. Medium-sulphur coke is showing more strength, out for \$2.90, a fairly stiff price seeing that standard coke is only \$3.

Heating coke is fairly steady, but demand is light and first drawings appear every now and then to disturb prices, sometimes going down to \$2.50, when producers would like to obtain \$2.75 on fair grades of heating coke. Foundry coke is rather dull but is quite firm at \$4 to \$4.50.

## Foreign Market And Export News

### Steadier Tone in British Coal Market; Output Jumps 521,000 Tons

The South Wales coal market reflects an increased steadiness of tone, with a slight improvement in inquiries, especially for large admiralty and bunker smalls. The volume of business, however, continues at such a low level that a number of operations are finding it difficult to work on a profitable basis. Therefore it would not be surprising if several collieries were to close down soon.

Output by British collieries, a cable to *Coal Age* states, registered a marked increase during the week ended Aug. 2, 5,010,000 tons having been produced, according to the official reports. This compares with a production of 4,489,000 tons during the week ended July 26.

British coal exports during the first half of 1924 declined 8,714,299 tons from the figures of the corresponding period in 1923, due to less buying on the part of Germany, Holland, Belgium and France, according to a report to the Department of Commerce by Trade Commissioner C. E. Lyon, at London. The United States took but 55,000 tons in 1924 as compared with 659,354 tons during the corresponding period of the previous year, when abnormal conditions existed.

### Spanish Mine Owners Would Limit Coal Imports

At a conference of Spanish coal producers held recently in Madrid it was decided to petition the government to institute measures to increase the use of domestic mined fuel. A strict tariff is recommended and also the erection of electric central stations in the neighborhood of pits. It is also proposed that foreign imports be limited, that all the national services (army, navy, etc.) and industries be compelled to use only Spanish coal and that the floating depots which are used for storing imported coal be abolished. The import duties and taxes adjusted so that Spanish coal will benefit at the

expense of the product of foreign mines. It is urged in support of the recommendation that Spanish miners are working only 5½ hours daily against 7 in foreign mines.

### French Domestic Demand Firm; Industrial Coal Week

The situation in the French coal market is unchanged. On the whole the demand for industrial coals continues weak, though it is increasing somewhat in some sections. House coals are in a satisfactory position and coal producers are committed well into the fall.

Deliveries of coke to the O.R.C.A. for the month of July amounted to 358,861 tons, or a daily average of 11,577 tons. For the first five days of August the deliveries through Ehrang and Aix-la-Chapelle were 39,525 tons, a daily supply of 7,905 tons. Deliveries are being curtailed at the request of French industrialists, who find themselves unable to find storage space for any more coal. Meantime fuel is being temporarily stored in the Ruhr.

The price of coke has not been changed and probably will remain on the present level (150.75 fr. all O.R.C.A. charges included) for the month of August.

Indemnity fuel deliveries for the first twenty-eight days of July to France and Luxemburg were 346,288 tons of coal, 454,689 tons of coke and 22,616 tons of lignite briquets, a total of 823,593 tons.

Agreements with the M.I.C.U.M. are to be prolonged on the following basis: (1) Gratuitous deliveries of reparation coal will be continued as in the past. (2) Licenses and derogation levies will be reduced by 50 per cent as of Aug. 1. (3) The coal tax is reduced to 25 pf. per ton from Aug. 1. (4) The coal tax for July is reduced to 50 pf.

This agreement has been renewed

until such time as the Dawes plan is put in operation. However, as from Aug. 15, the Commission of the Six (German industrialists) will have the right to denounce this agreement on five days' notice. When these accords were renewed on June 30 the different taxes and levies had already been reduced 50 per cent. This further reduction will oblige France to finance deliveries a little more than during the past by an increased deduction from the guarantee funds. It is not known yet in what measure the Reich will intervene financially, but its intervention seems now quite feasible as its budget presents a credit balance.

## News Items From Field and Trade

### ALABAMA

The Dixie Coal Mining Co. is erecting a new washery at the McCollum mine, Walker county near Jasper.

A state-wide first-aid meet will be held in Birmingham, Oct. 7, under the auspices of the U. S. Bureau of Mines and the Alabama Coal Mining Institute. Teams desiring to participate in the meet must file applications with J. J. Forbes, U. S. Bureau of Mines, Federal Building, Birmingham, Ala., on or before Sept 15.

The Sayre mines, in the western part of Jefferson County, Alabama, near Birmingham, belonging to the Gulf States Steel Co., are the first coal mines in Alabama to protect thoroughly the interior of the mines with limestone dust, 20,000 lb. of limestone dust being used.

The new development work of the Moss and McCormack Mining Co., near Carbon Hill, Walker County, is making good progress, an extension being made to the new mine from the spur of the Frisco Railroad serving No. 11 mine of the Calloway Coal Co. The company has opened an office at Carbon Hill and C. E. Crandell is superintendent in charge of the work. The lands on which the development is being made were obtained from the federal government when the royalty rights were auctioned by the land department a year or more ago.

### ARKANSAS

Scranton Anthracite Coal Co. is pumping out its mine and will soon resume.

### COLORADO

The thirty coal salesmen for the Colorado Fuel and Iron Co. spent a week early in August visiting the company's mines and comparing notes at the headquarters in Denver.

Three 500-ft. entries have been driven by the Moffat Coal Co. in the Elkhead country and a wagon road is being built. The coal is said to be a fine grade of anthracite. It is hoped to have a railroad built to the mine by the time the great Moffat tunnel is completed.

An explosion in the new Alamo mine near Walsenburg, early on the morning of August 5th, killed Alex MacBirnie, a fireboss and shut down the mine for a week. The man was alone at the time of the explosion. His body was found partly covered by a fall of the roof. There were evidences all around indicating that an explosion had been generated at that spot. The mine

which is still in its development stage, was not seriously damaged according to Harry F. Nash, general manager.

G. W. Harris of Denver, president of the Colorado and Utah Coal Co., is back at his desk after suffering a broken leg, sprained ankle and lacerated scalp in an accident last month. An automobile struck him as he was riding a horse. He was thrown clear over the machine and the horse capped the climax by falling on him.

The Bluff Springs Coal Co., which operates south of Florence, is making expansions and improvements. A spur will be built from the Santa Fe branch at Nushaft to the Bluff Springs mine, a distance of 2,200 ft. The old Donnelly slope has been taken over by the company, and a tippie will be built to accommodate it.

Two recent reorganizations in Colorado coal companies have been effected. W. W. Cowdery becomes president and general manager of the Crown Fuel Co. with a mine near Gorham. R. A. Pierce, former general superintendent and part owner is now chief engineer for the Colorado and Utah Coal Co. and W. A. Snyder, former general manager leaves the company. The Leyden Coal Co. also has undergone a shrinkage of executive forces. General Manager W. D. McCausland and General Supt. James Virgin withdrawing. John A. Sire is general superintendent and operating head of the mine organization. The entire sales force has been dismissed. The output will be sold by the Barnett Fuel Co. of Denver, wholesalers.

### ILLINOIS

A fire recently wiped out the business section of Freeman, a small mining town six miles southwest of West Frankfort. The damage is estimated at \$35,000. Ten frame structures, including seven business houses, a garage and two dwellings were burned. A change in the wind at the height of the fire was credited with saving the entire town from destruction.

### INDIANA

Enos Coal Co., of Cleveland, Ohio, has purchased 145 acres of coal land near Petersburg from R. R. Williams of Evansville and \$100,000 of land from several other holders.

The McClelland Coal Co. has announced that its mine south of Terre Haute would re-open after several months' idleness. Two hundred men will return to work and within a short time from fifty to one hundred more

men will be placed at work there. Several of the larger mines in the Terre Haute-Clinton fields and in the field south of Terre Haute, recently have resumed operations.

### KENTUCKY

The Kentucky Railroad Commission on Aug. 1 granted permission to the Chesapeake & Ohio R.R. to operate the Long Fork, Millers Creek and Ashland Coal & Iron Railroads, which the C. & O. arranged to take over some time ago, as feeders in its eastern Kentucky territory.

Announcement has been made by Willard R. Jillson, Kentucky geologist, of a new book to be issued shortly, on "The Mountains of Eastern Kentucky," as prepared by Professor D. H. Davis, geographer of the University of Minnesota, who has spent several summers studying Kentucky coal, oil and other resources. Coal, says Professor Davis, was noted in the Kentucky basin by Christopher Gist as early as 1759.

Reports from Owensboro state that the new Owensboro, Rockport & Chicago Ry. Co., which has asked the Interstate Commerce Commission for right to build a bridge and eighty-four miles of road to Elnora, Ind., there connecting with the Chicago, Milwaukee & St. Paul to the North and Northwest, is also discussing plans for building the line to Central City, Ky., in the heart of the western Kentucky coal fields.

The Hardy-Burlingham Mining Co., at Hardburley, Lotts Creek, Hazard field is said to be planning to make new openings and increase capacity. The company is said to have the largest capacity wooden tippie in the field, and its output does not nearly equal its capacity. It was also reported that the East Kentucky Coal Co., at Fusonia, Ky., had resumed operations, with some large orders, after being down for months.

The State Tax Commission has certified to the auditor of public accounts and the county courts the assessments on five companies in Pike County and one in Hopkins County. All assessments are considerably higher than heretofore. They are as follows: Edgewater Coal Co., \$577,592; Big Sandy Co., \$1,225,010; Consolidation Coal Co., \$1,028,167; Colony Coal & Coke Co., \$393,610; Fordson Coal Co., \$2,975,028. The St. Bernard Mining Co.'s Hopkins County assessment is \$2,393,497.

Engineers have located on the headwaters of Elkhorn Creek, Letcher County, to make surveys for a link be-

tween the Louisville & Nashville R.R. and the Carolina, Clinchfield & Ohio R.R. under a lease approved by Interstate Commerce Commission but not yet accepted by the L. & N. The line if constructed will run from McRoberts, Letcher County to Elkhorn City, Pike County and will give it is said the southeastern Kentucky fields a new outlet, a Gulf Seaboard market and an extended operating area.

## MINNESOTA

The Reeves Coal and Dock Co., which is constructing a new dock at Superior, Wis., has announced that the new dock will be in readiness by the opening of navigation next spring. The present dock which is under demolition will be out of the way early next month.

## MISSOURI

C. A. Norton, for the past four years secretary and treasurer of the Wallace Coal Co., has resigned to engage in another line of business in Chicago.

Harvey L. Salmon, for many years connected with the fuel department of the Missouri Pacific R.R., has recently resigned to engage in the auto-painting business in the northern Pacific coast. He is associated with B. F. Bush, who recently resigned from the Missouri Pacific as president.

## MONTANA

David Phillips, Henry Brauenstein and Henry Unschied, all of Minneapolis, have reorganized the Gilbert & Crawford Coal Co. operating mines at Roundup.

## NEW MEXICO

The Hagan Coal Mines, Inc., has connected its new mine, 30 miles from Albuquerque, with a Santa Fe spur and is bringing the mine up to a larger production. A steel tippie is now getting its final touches. W. H. Stark of Orange, is interested in this mine.

## OHIO

H. H. Heiner, formerly president of the Maynard Coal Co., who has been out of the business since that concern went into the hands of receivers, has been seriously ill with ptomaine poisoning at his home. He is now believed to be out of danger.

Joe Richards, general manager of the Blue Diamond Coal Co.'s mines, who has been ill for the past 15 months, a large part of which was spent in a hospital at Lexington Ky., is able to be about once more and is convalescing near Winchester, Ky.

The Southern Ohio Coal Exchange reporting for the week ending July 22 shows a total production of 79,279 tons from 439 mines reporting, which had a combined capacity of 638,285 tons. This leaves a shortage of 559,006 tons. Labor shortage was responsible for a loss of 8,583 tons; strikes, 8,825 tons; mine disability, 5,075 tons and "no market" 536,523 tons.

Following a series of meetings of the officials of the Southern Coal & Coke Co. it is said that N. L. Mahan, sales manager at Cincinnati, will resign as of Sept. 1 and will be succeeded by Louis Stone. E. L. Gatliff is slated to become secretary of the company. It is also understood that one of the group of mines of the Southern has been sold and another is on the market. On the other hand there is said to be a move on foot to consolidate still more mines with this group.

Imposition of a tax on every ton of coal mined in Ohio has been suggested by the Ohio State Teachers' Association as a means of financing the schools in mining districts of the southern and southwestern sections of the state. In spite of the great natural wealth of the mining districts, revenues received from taxation are totally inadequate properly to finance the schools.

The Association says that in the schools districts of the mining sections, the coal in the ground is listed for practically nothing, though, a steady stream

of wealth pours forth on which no taxes are collected.

Grover C. Angel, sales manager for the Main Island Creek Coal Co. for several years past, has resigned. B. Lee Hutchinson, who was largely instrumental in the consolidation of the various entities of the Hutchinson Island Creek Coal Co. will take over this work as general sales manager. Main offices in Cincinnati have been engaged and a further change may be made in the name of the corporation. "Big Mac" McAllister, who had charge of the Main Island Creek mines, with headquarters at Omar, W. Va., it is understood, will direct the mechanical affairs of the new organization.

Columbus operators were notified recently that the Hocking Valley R.R. has placed an embargo against all coal from connecting lines, even the Chesapeake and Ohio, of which the Hocking Valley road is a subsidiary. The reason for this action, which is unusual at this time of the year, is that the Hocking Valley has 5,400 cars of coal on the line between Columbus and Toledo. The congestion is due to the fact that many boats have been withdrawn from service at Toledo, so that the coal cannot be taken to the docks in the Northwest as rapidly as it is received at Toledo. Some boats have been taken off temporarily as the owners do not care to take coal up the lakes unless there is a downward bound cargo of iron ore and the movement of ore is light at this time.

## PENNSYLVANIA

Thomas J. Bray, of Youngstown, Pa., president of the Republican Iron & Steel Co., suffered a heat stroke Aug. 10, at the Oakmont Country Club, Oakmont.

Stock in the Lehigh Valley Coal Co. is being sold to employees on the monthly payment plan, deductions being made on the payroll on request of the applicant at the rate of \$3 per share per month, instalments paying interest at 6 per cent.

Production in central Pennsylvania for the week ending Aug. 9, was 11,482 car loads, as compared with 11,330 car loads for the previous week. The total production for August to and including the ninth, was 14,234 car loads, against 12,129 cars for the same period in July. However, the July period had a holiday season which cut down the production.

Miners employed by the Consumers Fuel Co. at Harmarville struck Aug. 7, a few days after they had returned to work after a six-weeks' lay-off due to lack of orders. The strikers complain against working conditions and agreements. Officials ordered the men to take their tools and leave the workings.

The State Workman's Compensation Board has dismissed the appeal of the Pennsylvania Coal & Coke Co. from the award to the widow of Mike Harchuck who died of blood poisoning. When working on a pipe line his fingers were hurt and death followed a few weeks later. The company contended,

Courtesy U. S. Distributing Corp.

## Tippie at Dietz, Wyo., of Sheridan-Wyoming Coal Co.

In the northern part of Wyoming is a coal area known as the Sheridan field, it being named after the principal town of the northern half of the state. The principal centers in this coal area are Sheridan, Acme, Carney, Monarch, Kooi and Dietz. The field is adjacent to the Fort Mackenzie Military Reservation.

and presented testimony tending to show, that his blood had been poisoned in a blood-letting operation.

Two miners lost their lives Aug. 6, three others were seriously injured and one hundred miners had narrow escapes when a rock-fall occurred in Springfield Mine No. 1 in Nant-y-Glo, Cambria county. The fall occurred just as the day shift was entering the mine, in a trip of twenty mine cars. They were one half mile from the entrance when many tons of rock gave way, burying two of the wagons.

The Neilson colliery, at Shamokin, which has been acquired by a group of Wilkes-Barre investors, has been re-financed and work is to be started shortly. It is estimated by the company's engineers that with sixteen beds of coal, about 24,000,000 tons of virgin coal is available. The improvements to the present operation include an electrically equipped breaker, capable of preparing 1,500 tons of coal daily.

Two deaths were caused within a few minutes Aug. 10 by a high tension electric wire at the entrance to the No. 3 mine of the H. C. Frick Coke Co. at Mt. Pleasant. One of the fatalities occurred when a man who had gone to investigate the death of the first victim, a boy, lost his balance and seized the wire as he fell.

The boy was picking coal, when in some undetermined manner, he came into contact with the high voltage wire.

The Northwestern Mining & Exchange Co. and the Blossburg Coal Co., of DuBois, Pa., announce the signing of a contract with the Peabody Coal Co., by which the latter company will continue to manage the mines of the former companies for a period of ten years. The Blossburg Coal Co. has three mines which produce a total of 1,000 tons per day. Seven mines of the Northwestern Mining & Exchange Co. yield 5,000 to 6,000 tons daily. The new Kramer mine of this company is involved in the contract. At present it is producing only 400 tons of development coal per day. It is equipped to handle 4,000 tons per day; early in the fall it will start to run room-and-pillar coal. When running at capacity all these mines will produce about 10,000 tons of coal per day.

## WEST VIRGINIA

The E. E. White Coal Co. has had for several months a blanket insurance on the life of every one of its employees. The family of a colored employee, who died at Glen White recently, is the first beneficiary.

The Island Creek Coal Co. has completed work on a new steel tippie at its No. 14 mine at Holden, W. Va., which mine is again in operation. A new steel tippie replacing an old wooden structure at No. 1 mine of the Main Island Company at the mouth of Trace Fork has also been completed.

The Flat Top Fuel Co. of Bluefield, W. Va. shipping Pocahontas, Tug River and New River coals, over the Norfolk & Western, the Chesapeake & Ohio and Virginian railways, established a new

world record a few days ago when the British steamship Polovera passed out of Cape Henry en route to Rio de Janeiro, Brazil with 13,599½ tons of coal, the largest tonnage, according to official records, ever loaded on a single ship at the Norfolk & Western piers. The cargo so shipped was valued at about \$53,000.

Tenants will be evicted by the Charleston Coal Mining Co., at Handedley, and by the Coalburg-Kanawha Coal Co., at Coalburg, in order to make way for non-union miners. These mines which made a contract with the union are now attempting to work on an open-shop basis after trying to obtain a wage concession.

Experiments are being conducted by the Bertha Consumers Coal Co. at its Rachel mines at Downs in northern West Virginia with a special type of conveyor, designed by attaches of the company and made by the Fairmont Mining Machinery Co. The conveyor works on a 45-deg. face similar to that used in the V system. Joy and Myers-Whaley loaders are being used at the Eureka mine, Randall, Monongalia county.

Several diamond drills are at work and crop-coal openings are being cleaned out in the Richmond district of Raleigh county. This is regarded as evidence that the railroad up Glade Creek will be extended and more New River coal developed.

The large store and office building, the recreation hall and several residences occupied by department heads of the Superior Pocahontas Coal Co. at Davy, McDowell county, W. Va., were totally destroyed by fire during the closing days of June. The combined store and office building was constructed of native sandstone and three stories high. The loss sustained is about \$100,000. The company will rebuild.

The Brotherhood of Locomotive Engineers has filed an application with the Interstate Commerce Commission for authority to operate the Coal River & Eastern Ry. in interstate commerce between the Coal River Collieries, which are owned by members of the brotherhood, and the Chesapeake & Ohio Ry. The Brotherhood has \$3,000,000 invested in coal properties in southern West Virginia. The application of the Brotherhood is being opposed by the C. & O., which contends that the line is simply a spur and not a part of an interstate transportation system and that the proposed capitalization of \$1,500,000 of the Coal River & Eastern Ry. is grossly exaggerated, the value of the surface rights not being \$750,000 as claimed.

## WISCONSIN

The Great Lakes Coal and Dock Co. has leased the docks in Milwaukee, Wis., formerly occupied by the Central Coal Co.

Paul Galleher, city agent for the Northwestern Fuel Co. at Superior, Wis., has left for St. Paul where he will be in charge of one of the company's city offices. Charles A. Rogers will succeed him.

## WYOMING

The Wyoming & Colorado short line railroad has asked the Interstate Commerce Commission for authority to construct a line from Casper south-west to the state line between Colorado and Utah, 381 miles long. Iron and bituminous coal fields will be traversed by the railroad if built.

## CANADA

On Aug. 2 an explosion occurred at the Midland Collieries, Drumheller, Alta., causing the deaths of three men, Harry Duhockle, outside foreman, James Nichol, pit boss, and Griffith Richards, pump boss. Malcolm Richards, fire boss, was gassed.

Many of the Toronto coal dealers with yards along the water front and in the north-west section of the city are looking for new locations as a result of the work that is to be started on the lake front viaduct and subways in the vicinity of Bloor St. West. Considerable difficulty is being experienced in finding suitable properties with railway sidings.

## New Companies

With a capital of \$25,000, the **Hatfield Coal Co.**, Covington, Ky., has been chartered by J. T. Hatfield, Charles A. Hunt, and M. H. McLean.

The **Sharon Pond Creek Coal Co.**, Sharondale, Ky., capital \$100,000, has been chartered by William York, Elva H. York and A. B. York.

Papers have been filed with the secretary of state increasing the authorized capital of the **Cleveland & Morgantown Coal Co.**, of Cleveland from \$1,500,000 to \$2,000,000.

The **Diamond Coal and Coke Co.** has been organized at Pittsburgh; capital \$5,000. Incorporators: C. F. Kiefer, Pittsburgh; J. D. C. Miller, Dormont; David E. Meigs, Swissvale.

The **West Coast Collieries Ltd.** has been incorporated with a capital of \$525,000 and head office in Toronto. The company will operate throughout Canada. Arthur W. Holmstead, Douglas L. Ross, Leonard V. Sutton and others are incorporators.

The **Mender-Patton Coal Co.**, 77 W. Washington St., has been chartered with an authorized capital of \$10,000 to mine coal and deal in coal and coke. Incorporators are: William F. Patton, Hazel G. Patton, Earl D. Mender, R. D. Graham and Carl Mathews.

The **Peerless Elkhorn Coal Co.**, chartered recently with an authorized capital of \$150,000, has been organized by the election of F. G. Hatton, president; W. M. Brown, vice-president and George S. Schwartz, secretary. The officers are the same as of the Hatton Brown & Co., Inc., of which company it will be a subsidiary. The new concern has acquired two large properties with two working mines in the Elkhorn field of Kentucky, located on the Big Sandy division of the Chesapeake & Ohio RR. Extensive improvements will be made to increase the capacity of the mines.

## Traffic News

### Perry County, Illinois, Operators Seek to Have Freight Rate Sustained

Sixteen coal companies of southern Illinois, including the Perry County Coal Co., are endeavoring to have sustained a reduced rate on coal recently ruled by the Interstate Commerce Commission. The Alton & Southern Ry. and a dozen other companies are contesting the decision before Circuit Court Judge Crow, of Belleville, Ill.

The freight rate on coal for a thirty-mile haul is to be reduced, if the County Court permits, from 91c. to 70c. per ton and for any distance from thirty to seventy-two miles to 80c. per ton. The railroads say these rates will not be remunerative. The new tariff is ordered for Aug. 25.

### Fight For and Against Twin City Freight Rate

The Twin City Rapid Transit Co., operating the street railway system of these cities, has entered its protest against the revised freight rates on all rail coal, to the interstate commerce commission, following similar action by the Hydraulic Press Brick Co., Minneapolis, the Waldorf Paper Products Co. and the Northern States Power Co., all as large consumers of Illinois coal. On the other hand, the Northwestern Coal Dock Operators' Association has entered a protest against a rehearing of the case. It is still an open question whether there will be enough pressure brought to bear upon the commission to induce a suspension of the new rates on all-rail coal, effective by Sept. 10. Hints have been made of a possible injunction being asked to prevent the rates going into effect.

Superior, Wis., through its city commission, is starting an investigation to determine whether the city is being discriminated against in the matter of coal freight rates.

### Revision of Dockage Rates

The Public Service Commission of New York State has approved a charge on New York Central Lines of 25c. per net ton for unloading from vessel, handling from dock and dumping into lighter on bituminous coal arriving by vessel at West Shore Coal and Ore Dock, Buffalo, and transferred by machinery and other facilities furnished by the West Shore R.R. An allowance of 17c. per net ton will be made to the Ashtabula & Buffalo Dock Co., contractor, for service performed in handling the coal as described above.

## Trade Literature

**National Arches.** M. A. Hoff Co., 814 West Washington Ave., Indianapolis, Ind. Pp. 15; 8 x 11 in.; illustrated. This booklet points out the lower maintenance costs with the use of these arches, their outstanding advantages, ease of installing and replacements.

**American Cast Iron Storage Tank.** Conveyors Corporation of America, Chicago,

Ill. Pp. 11, 4 x 8½ in.; illustrated. This is a sectional tank for the storage of dry, loose, bulky material, such as ashes, coal, etc. The booklet contains table of weights, measures and capacities.

**Manganese Steel Castings for Mines.** American Manganese Steel Co., Chicago Heights, Ill. Catalog No. 5. Pp. 76; 8 x 11 in.; illustrated. Covers the use of manganese steel castings for ball and tube mills, buckets, conveyors, crushers, shovels, etc.

**Wanghammers.** The Denver Rock Drill Mfg. Co., Denver, Colo. Pp. 15; 6 x 9 in.; illustrated. This bulletin is devoted chiefly to describing Model 93, a wet or dry sinker, and Model 95, a dry sinker. Model 37, heavy duty sinkers, drifting drills, stopers, drill steel sharpener, drill steel puncher, and comparascope are among the equipment mentioned.

**Industrial Lubrication.** Waverly Oil Works Co., Pittsburgh, Pa. Pp. 44; 3½x6½ in. The lubrication charts in the back of this book should prove interesting to anyone who has to do with the lubrication of machinery.

**Heine Cross-Drum Boilers.** Heine Boiler Co., St. Louis, Mo. Bulletin No. 53. Pp. 29; 8x11 in.; illustrated. Describes the M and MC types of Heine boilers, the former equipped with horizontal baffles and the latter with cross baffles.

**Tramrail.** Cleveland Crane & Engineering Co., Wickliffe, Ohio. Catalog No. 3 Pp. 220; 8x11 in.; illustrated. Describes system of hoisting and conveying loads for warehouses, etc.

The Crouse-Hinds Co., Syracuse, N. Y., recently issued the following bulletins: **New Ideas in Electric Hand Lanterns.** Folder No. 10. **Vaporproof Condulets with Reflectors.** Bulletin No. 2057. **Condulets for Concealing in Concrete.** Bulletin No. 2059. The bulletins are 4x9 in., illustrated.

Sullivan Machinery Co., Chicago, Ill., recently issued the following bulletins: **Vacuum Pumps.** Bulletin 78-B; 11 pp.; describes its straight-line steam-driven and belt-driven vacuum pumps for vacuum service. **Belt-Driven Air Compressors.** Bulletin 77-K; 16 pp.; describes the Sullivan belt-driven wafer-valve air compressors, class WG-6 single stage and class WH-6 two-stage. This company also has issued new editions of Bulletin 77-H, **Angle Compound Compressors**, and Bulletin 70-X, **Compressed Air Spader.** These bulletins are all 6x9 in. and illustrated.

## Obituary

**John P. Hebenstreit**, aged seventy-five, superintendent and vice-president of the Illinois Coal Corporation, recently died of apoplexy, at his home in Nokomis, Ill. He was one of the well-known coal operators of Illinois and had spent years in the coal mining industry.

## Coming Meetings

**New York State Coal Merchants Association, Inc.**, 14th annual convention, Sept. 4-6, Stamford-In-the-Catskills, N. Y.; headquarters Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

**American Chemical Society.** Fall convention Sept. 8-11, 1924, at Ithaca, N. Y. Secretary Gas and Fuel Section, O. O. Malleis, the Koppers Co., Pittsburgh, Pa.

**Oklahoma Coal Operators' Association.** Annual meeting Sept. 11, 1924, McAlester, Okla. Secretary, A. C. Casey, McAlester, Okla.

**Association of Iron and Steel Electrical Engineers.** Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Oxygen Manifold Has Valve That Cannot Blow Out

What is said to be an absolutely foolproof valve for oxygen manifolds has been devised by the Oxyweld Acetylene Co., of 30

East Forty-Second St., New York City. The body has a formed seat receiving the stem tip 2. This tip is attached to and carried by the stem 4, by means of a swivel joint. Thus, the tip is enabled to seek its own natural seat in the body. The stem screw is in the inner end of the stuffing box 6, which is made gas-tight into the body by means of a lead gasket. The stem itself is made

### Safe Manifold Head

Stem screws into stuffing box and so internal parts cannot be blown out by pressure.

Itself is made gas-tight by the rubber packing, which is compressed between packing rings by means of the handwheel and nut.

If the operator should happen to unscrew the handwheel all the way, there is no possibility of the internal part being blown out by pressure, because the stem screws into the stuffing box. Even if he should unscrew both the stem and the handwheel, the parts could not come out because the large end of the stem would lodge against the inner end of the stuffing box.

### Power Plant for Gassy Mines Moved Around on a Truck

The first approval of a portable electrical power plant for use in gaseous mines has been given by the Bureau of Mines, to the Mancha Storage Battery Locomotive Co. and covers a special truck of locomotive type containing battery cells of sufficient number and capacity to operate a coal-cutting machine.

One of the chief causes of electrical accidents in coal mines is sparking or arcing of electric wires. A wide application of the storage battery may be the solution of this problem by doing away with all permanent wiring in gaseous or dusty mines.

The advantages claimed for the portable power plant are that it permits the elimination of feeder circuits and that it gives more rapid and satisfactory operation of the mining machine, owing to uninterrupted power supply and non-fluctuating voltage.

The power truck has a single motor connected to both axles by a worm and

gear. Its weight complete is from 10 to 12 tons. The battery equipment available differs for the various types which may be used.

An individual service plug and receptacle is provided for connection of the mining machine cable to the battery. The mining machine circuit is fused at the battery box with the same type of combination fuse and switch as is used for the main circuits of the truck. With this arrangement the power can be cut off from the mining machine either at the cable reel or at the battery. The service plug is locked in place by means of a padlock, and therefore the power truck and coal-cutting machine operate together as a unit.

The motor, controller, resistance, main fuse box, headlight, headlight

**Power Plant on Wheels**

Taking the power plant to the motors may seem to be a novel experiment to some of us, but in gaseous mines or places rapidly developing, much of this is done.

switch, headlight fuse box and ampere-hour meter housing, after having been subjected to rigid inspection and tests in explosive mixtures of Pittsburgh natural gas and air, were judged to conform to the requirements of Schedule 15 of the Bureau of Mines, which states the procedure for establishing a list of permissible storage-battery locomotives for use in gaseous mines.

Like the flame safety lamp or any other safety equipment, the power truck can be relied upon as being safe only so long as it is carefully inspected and maintained in a safe condition. The approval plate specifically mentions points to be observed in keeping the equipment in a permissible condition.

### Stoker for Small Boilers

Small coal mines have thus far not found stokers suited for use under their small boilers and accordingly usually have burned large coal wastefully and with heavy firing losses. Furthermore all industry has been similarly situated, also apartment houses which use boilers for heating.

The Stoker Sales Co., 650 Old Colony

### To Burn Screenings Smokelessly

This stoker makes it easy to burn small sizes, saves loss of coal to ash pit, and heat losses in firing. It also makes the use of poor coal profitable.

Building, Chicago, has introduced a stoker, designed by Joseph Harrington, to burn screenings or any coal below the grade of No. 2 under a boiler, consume it smokelessly and transfer the ashes into a receiving hopper. This stoker, known as the King Coal, is constructed for boilers in sizes ranging from 250 hp. downward and is well suited for western screenings. It has a reciprocating plate carried on rollers which has a travel up to 5 in., the length of travel determining the quantity of the coal fed. The grates are terraced or stepped, the first set of grate bars resting and sliding over the second step of the grate. The first and third grates have a forward and backward sliding motion (their action being simultaneous) and the second and fourth grates are stationary. By this motion the grate bars literally slide out from under the coal, the bed of coal being disturbed only by its fall over the ends of the grate bars. Because of this action, even coal with coking properties can be burned and with an efficiency said to be equal to that obtained from non-coking coals.

The plate or table directly under the ash opening at the rear supports the body of ash as it falls from the fourth grate. Having a reciprocating action it provides also a slow but definite travel of the ash toward the front, but as it at all times fills the throat or ash opening, that opening is always sealed against an inrush of cold air. By the use of this stoker most of the heat in the ash is utilized and complete combustion made possible.

Either natural or forced draft can be employed. The stoker is operated by a  $\frac{1}{2}$ -hp. motor or by a hydraulic drive of equivalent power.

### Starter for High Torque Duty

A new manually operated, inclosed type resistance starter suitable for starting squirrel-cage induction motors as large as 20 hp. on 550-volt circuits,

### Safe Inclosed Motor Starter

Being manually operated but inclosed, this new starter is suitable for use wherever inexperienced labor is employed. The overload trip may be reset without opening the cabinet by pulling a chain hanging from the bottom of the box.

### Coal Steadily Fed Forward

Second and fourth steps of grate are stationary; the ash step and first and third steps reciprocate. Grates slide out from under coal. Quarter horsepower motor drives grate.

has recently been developed. The resistance is proportioned to give an inrush current three and one-half times the normal full load motor current, thus permitting the motor to develop at least 50 per cent of its full load torque while starting.

The starter is made by the General Electric Co. and is of the safety type, completely inclosed with ventilated case, externally operated and provides overload and undervoltage protection. It is furnished with a single-step resistor, equal parts of which are connected in each phase. The switching elements are of the contact finger type, strong and readily renewable.

## Our Ventilation Notions

EUGENE McAULIFFE, as usual, looks ahead of his contemporaries. Our laws are based largely on non-gaseous conditions. They provide rules to keep our mines free from "noxious gases," the carbon dioxide and the unburnt gases of the long discarded oil-flame torch and from the gases from explosives burned and partly burned. Still the logic of making the quantity of air dependent on the number of men has some validity. Where there are more men, there are larger areas to ventilate and as more coal is broken, more gas is made.

However, the logic at best is bad. The better plan is to base the quantity on a fixed minimum per man with a requirement that the methane in the return be less than a given percentage. Today we can measure the percentage of methane and it should be determined, the ventilation being made dependent on it. Furthermore the air should be well distributed. Our anemometers are poor instruments at best in a sluggish current. If they had been better, we should have found mine inspectors long ago insisting on men receiving at their working places the minimum quantity required by law. Unfortunately, even now it is impossible for them to make any such demand. They could not measure the air even when it is supplied, so they are obliged to satisfy themselves by insisting that the air passing the last crosscut of an entry shall be enough to supply all the men working on that split, not a very satisfactory requirement, as we all know.

## We Have Skimmed the Cream

EUROPE builds for generations. It anticipates that it will continue mining seam after seam till all is mined, whereas we are merely skimming the cream. In most cases we have assumed that there is only one good and workable seam in a hill. Perhaps there is but one today, but there will be more tomorrow, for by the time one seam is exhausted, another, or more than one, has become valuable by reason of the general depletion of the thicker, cleaner measures available for operation.

In the anthracite region seven or eight seams, one above the other, are being mined. In the Connellsville region the Pittsburgh seam is becoming exhausted and the Sewickley is being attacked. In the Georges Creek field the Big, or Pittsburgh, bed has had its day, and the Tyson, or Sewickley, thin as it is, is being mined. In the Clearfield region, the Moshannon, or "D," bed has almost disappeared and mining in the Lower Kittanning bed and other seams has followed. These are a few examples but there are many others.

Why not build like Europe, as far as houses are concerned—for generations? We believe that practice will become general as the cost of lumber increases and

deeper—and therefore more extended—beds are attacked. The miners, in America, live in frame houses and own automobiles. In Belgium they live in well-designed residences and own bicycles. Someday, perhaps we shall be somewhat like-minded, and better housing will be customary.

However,—and here we hedge—as our rate of extraction is speeded we probably shall continue to face the difficulties that are part of such rapid extraction. Our villages cannot be permanent, if a few short years end their usefulness.

## "It Can't Help It"

AFTER outlining a new scheme to the superintendent or manager for effecting a saving in operation or maintenance, the electrical or mechanical man is asked, "How do you know it will work?" Characteristic replies are, "Well, it looks like it ought to," and "It can't help it."

Is it difficult to guess which reply is from the "cut and try" man, and which is from the man who has made a careful study of his line of work? The fast-passing "Let's try it" type may become a fairly valuable man if he lives long enough and is fortunate enough to be able to continue performing costly experiments at the company's expense.

Today we must reduce labor costs; this requires the use of more and newer types of machinery. The cost to own and maintain this equipment tends to offset the labor saving. How can the margin be increased? Putting the supervision of the mechanical and electrical equipment into the hands of a man who has the required training and experience may be the solution. At times of low profit costly mistakes are unusually distressing.

## The Private Police Nuisance

PRIVATE police we are told are an anomaly not contemplated by the fathers of our country. Whether that is true or not, the private hiring of police is not desirable and is comparable to employment of retainers on feudal estates. To each baron was left the task of keeping order, and he did it by maintaining armed men in or adjacent to his castle.

It was not a happy way of solving the situation. With the passage of time it was ended. The state became strong, it provided its own guards, and the law was better maintained. We condemn feudalism, but it was better than disorder. It was the only hope in those disorderly times. Where the state is strong and vigilant there is little need for feudal retainers or armed guards.

When the rulers are prompt to enforce the law and repel disorder the land owner does not look for any other assistance unless he is desirous of subverting the law. But where governors are mere puppets of the

electorate, when their main concern is to keep not their oaths but their votes or the votes of the party, private police are almost inevitable.

The duty of the state is to maintain order and not to mend it after it is broken and the damage is done. If this is not the law it should be or we shall drift into feudalism insensibly. Even now in banks we have armed detectives and armed employees. We have our armored cars and armed men traveling the streets on behalf of banks as well as on behalf of the U. S. government.

At the mines also we sometimes have armed guards. It is distinctly unfortunate, but usually in such cases the state is weak, venal or penurious, and the people suffer. The fault is with the state. The crime is that of the politicians, no matter how diligently they may try to place it elsewhere. If we have feudal weakness at government centers we shall have feudal conditions throughout the country. Feudalism was the outward sign of a disease known as defective nationhood.

### Talking Through the Ground

THERE are men in the coal industry who scoff at the news that an Illinois high school teacher and a bunch of his boys have perfected radio equipment and a circuit by which telephonic communication can be set up between a mine and the surface. They say: "What's the use of it, even if it does work experimentally? There would only be a one-in-a-million chance that miners caught in a blast could get to one of the underground radio telephone sets, and even if they did, it wouldn't do much good, for relief parties can do a good job of locating imprisoned miners as it is."

This is somewhat idle talk. It is a well known fact that relief parties cannot always locate imprisoned men easily. In fact they often cannot locate them until they are all dead. If Mr. McCall and his boys—and girls; for there are four in the Springfield High School Radio Club—have made it possible for men on the surface to talk straight down through the ground to points in a mine directly beneath their feet, something beneficial has been done for mine rescue work. Let there be no mistake about that.

Even if miners in an explosion had only one chance in a million to get into a radio-equipped refuge chamber, still the device would be worth while, for a human life is precious. But the chances would normally be a great deal better than one in a million. And what would be the cost of properly equipping a mine? This cannot be said definitely. Permanent installation and maintenance would add something, but whatever the cost, it probably would be modest in comparison with the value of lives of men. So if these Springfield boys actually have done something constructive, let their elders in coal mining recognize it. In fooling with radio, the boy is always likely to do the thing a man thinks is impossible.

Nearly every invention starts hampered by limitations that make it of doubtful utility. But the step once taken, experiment follows and the limitations are one by one lessened or removed. "What use is it?" is not the appropriate question, but rather, "Of what uses may it be as conditions change and limitations are removed?"

### Law and Sentiment

NO ONE CAN fail to appreciate that a right sentiment, as regards safety, is better than stringent regulation, but, unfortunately, the right point of view fares but badly in face of fierce competition. With prices as low as those now existing there is sure to be a tendency toward short cuts, the operator hoping that somehow the accidents which go with economies in management and method will somehow escape him. Sometimes he does escape them for months, even years, and then the fatal moment comes and he finds that he must pay the penalty of his evasions.

The Rocky Mountain Coal Mining Institute's safety committee, the report of which we publish today, lays stress on the possibilities of a sentiment created for safety, and the West has always shown an excellent spirit in this matter. It has for years regarded the laws as minimum provisions for safety and sought a more excellent maximum. That it has not attained safety has been due to the fact that the state of the mining art did not afford methods sufficiently safe to meet the unusual dangers of Western mines.

The failure of the West to avoid severe explosions has been due not to law breaking but to lack of knowledge of the way in which to avoid explosions. That lack of information was nation-wide and particularly distressing in the West because nearly all the problems presented themselves in their most acute form. In justice to the West, it must be said it has been disposed always to lead in safety methods, to devise new safety plans, to use its brains to anticipate trouble, but with all its effort, originality and willingness to engage technical graduates, it has not been able to keep its mines as safe as those in the East, due to the inherent dangers of the coal on the Rocky Mountain slopes.

But, however much we may approve the spirit of the West in general and that of the Rocky Mountain Coal Mining Institute in particular, we cannot endorse its sentiment toward the law. We want more and better laws, we should advocate them and not merely take an indifferent attitude to them. With the sentiment toward good practice, laws to enforce correct action on the few unwilling should make for better mines. The laws are antiquated, sometimes positively harmful unless disregarded, and they should be made more in accord with modern knowledge and practice and also more stringent. There are too many lawyers, doctors, butchers, and bakers, who do not know anything about mining, who own and control mines. There are too many catch-penny mine owners. The industry needs laws to control them and to quote to them. The better operators have to compete with these ill-instructed or ill-meaning men and desire that they shall have to meet the same bills for safety as other operators.

The other day the telephone bell rang. An operator at the other end of the line wanted to know if there was any law to prevent him from drawing the pillars on his main entry; the coal looked near and easy to mine. He was assured that there was no such law, but that he had better beware of any such practice or he would have no mine. This is an extreme case but with such men we need law, not, perhaps, to prevent that particular action, but to keep them from doing others not so obviously foolish but more harmful to the workman and to their business rivals.

Office and Bathhouse at the André Dumont Colliery

## Campine Mining Villages Resemble Garden Cities

Equipment Provided the Mines Without Stint—Koepe System of Hoisting Used—Permanent Materials of Construction Employed—Towns Artistically Designed by Skillful Architects—House Interiors Immaculate

BY D. ADAM  
London, England

UNUSUALLY liberal has been the equipment of the collieries in the Campine district of north-eastern Belgium. Modern machinery and appliances are housed in palatial buildings that have nothing of the cramped and crowded architecture characteristic of the older collieries. The streets and lanes of the upper works have given way to the "grands boulevards," where there is neither congestion of traffic nor accumulations of stores or materials. The engineer coming from the narrow galleries of the mine may be inclined to think that his brethren on the surface have run riot in the abundance of space that has been afforded them, but closer examination will satisfy him that all has been planned to lighten the labors of those below ground, whose working space is limited by a roof and floor little more than two ft. apart.

The workshops are designed to make the collieries, as far as possible, independent of outside engineering assistance. Not only has provision been made for all normal repair work, but for the manufacture of such equipment as mine cars, cages and small pumps. At the André Dumont colliery it is even proposed to install an electric furnace for making steel castings.

At nearly all the collieries, pulverized coal is to be used for boiler firing. It is estimated that this will save 25 to 30 per cent in fuel consumption. The Lim-

bourg-Meuse colliery has already two boilers equipped for burning powdered coal, and the results so far obtained have been highly satisfactory. A pulverizing and distributing plant is now under construction at Winterslag for supplying a battery of fourteen boilers.

### CAMPINE SHAFTS USE KOEPE HOISTING SYSTEM

One feature that specially strikes the visitor to these Campine shafts is the use of the Koepe hoisting system. This system is not much in favor with engineers outside Belgium and Germany, but in these countries it is strongly advocated for deep shafts, even those equipped with four-deck cages carrying eight cars of 600 kilos (1,323 lb.) capacity. One reason given for its adoption is that the coal is hoisted from different levels in the shaft and for such work the cylindro-conical drum is not suited.

In nearly every case when the production stage has been reached, electric hoisting engines are employed. Both underground and on the surface arrangements are made for the simultaneous loading of at least two of the cage decks. The shafts, as previously mentioned, are equipped with four hoisting compartments, and this also has been a factor influencing the choice of the Koepe system, for the space occupied by the engine and pulley is far less than that taken up by drums. The engines also can be placed alongside one another without excessive "angling" of the hoisting rope. The collieries generate their own electric power and are fitted with magnificently equipped central plants feeding the surface works and underground substations.

The baths provided for the miners are so luxurious, with their individual tiled compartments and showers, that their attraction must be irresistible even to those

NOTE—The André Dumont colliery shown in the headpiece is one of the newest in the Campine region although none are old in any sense. The employees enter the operation by way of the large doorway toward the right of the illustration. Surface workers may go direct to their respective places but the underground employees go to the shafts by way of the washhouse and bathroom. At the "inquiry windows" in the large hall the workman can get in touch with any department or receive instructions for the day's work.

Some of the Geological features and operating characteristics of the Campine field were described in the issue of Aug. 21 pp. 247-251.

FIG. 1

### Miner's Houses, Winterslag

Materials for permanent construction are abundant in this locality. Thus good stone for foundations, sand and gravel for making concrete, and clay for brick and tile manufacture may be found in the immediate proximity of the mines. As a result these materials are used freely in construction. Houses like these are not only neat and attractive but durable and the upkeep is almost negligible.

most firmly addicted to the family tub. A salutary Belgian law requires mine owners to provide change houses and baths for the miners, but it cannot compel the miners to use them. Some moral persuasion may be used, but it is rarely needed. The Belgian miner accepts the bath with thankfulness and would not tolerate the conditions common in British operations, where the miners, wet and dirty from their day's work, often have to travel long distances by train or trolley to their own and their fellow-passengers' discomfort. British tourists with the virtuous feeling engendered by their own devotion to the "morning tub," formerly spoke reproachfully of their Continental neighbors' neglect in this important matter, but, so far as the mining industry is concerned, the reproach is now all the other way.

The tourist inclined to adopt airs of superiority will learn another lesson in the Campine, perhaps still more humbling. The housing of the mine employees in this region is a model to the whole world, and a revelation to those familiar with the rows of squalid dwellings that surround the old-time colliery. Apparently, in former times, it was considered that the miner would be out of his element if the dirt and discomfort with which he was surrounded during his working hours were lacking in his hours of leisure. Another grave error of those days was to suppose that miners' houses could

be designed by an engineering draftsman, on the simple principle of drawing with straight edge and tee square a row of rectangles for the ground plan and another series of rectangles, with smaller rectangles inserted, for the front elevation.

The first plans for the garden cities of the Campine were made by engineering draftsmen it is true, and the inevitable rows of rectangles made their appearance. The land available—and there was plenty of it—was divided into squares and as each of these was a duplicate of the others, one detailed plan multiplied by blue printing served the needs of the building contractors. Fortunately wiser counsel prevailed, and architects were summoned. These men with greater skill and a finer artistic sense, designed the beautiful communities that today are springing up on the old waste moorlands of the Campine.

### WINTERSLAG MAKES SANDY SOIL PRODUCE

Winterslag already has a population of more than 4,000. A church is under construction as well as a school, eight hotels for bachelor employees, numerous cafés and canteens and the indispensable cinema or "movie." The sandy soil has been made fertile by dint of hard work and every house has its flower garden. The broad avenues and boulevards, laid out on graceful curves, are lined with trees and at every step there is something to attract and please the eye. It may be nothing more than a variation in a doorway or gable, or the style of architecture may be completely changed, but always the effect has been thought out and in every line there is evidence of the artist's hand.

Perhaps the cost was a little more than that of standardized rectangles, but so little more that no one with even the slightest perception of architectural beauty would give it a thought. One thing has helped the architect to obtain variety. Belgium is a democratic country and in her new-built cities of the Campine there are no Fifth Avenues or Park Lanes. The villas of the higher officials are, of course, more commodious and elegant than the miners' houses, but they are not set apart in some exclusive quarter for the aristocracy. On the contrary they are scattered here and there throughout the whole city and in the matter of postal address there is no invidious distinction between one street and another.

Inside the houses, the architect has been no less

Fig. 2—A Miner's Garden, Once a Sandy Waste

This "old world" garden located in the town of Winterslag, shows what can be accomplished in the way of transforming the sandy moors from a stretch of waste land into an attractive home. Intelligence, water, work and fertilizer did the trick.

FIG. 3

### Hotel du Parc, Winterslag

Several hotels such as this have been constructed. Here the single men of the mines can board for about 8 fr. per day. This is equivalent to approximately \$1.60 in our money at normal rate of exchange or about 40c. per day at the present exchange rate. A small and homelike hostelry is the Hotel du Parc. The Belgians believe that a house without a garden is a shed and not a home.

successful in his treatment, and Belgian housewives, famous for their spotless polished kitchens, are delighted with the opportunities afforded for the practice of their art. The husband who ventures to omit the change house and the bath on his homeward journey from the mine receives persuasion far more effective than any, moral or otherwise, that could be given him by the mine authorities. The accommodation in the houses is varied to suit different requirements. Large families are not unfashionable in the Campine, and generous provision has been made to house the young generation both in the homes and in the schools.

The colliery companies are building these cities with their own workmen. With a certain degree of assistance from the state in the form of loans at a low rate of interest, they have been able to build at a lower price than would have been possible had they employed an outside contractor. They were fortunate in finding close to the sites of their towns good sand and gravel for concrete, and clay for brick making. The provincial and local governments are contributing toward road building and drainage. Railway construction to meet the needs of this new industrial center is being provided by the Belgian State Railways.

To some, the expenditure entailed in building these garden cities may seem extravagant, more especially as the mines have not yet reached the stage of full produc-

tion. The mental inclination of the Belgian workman must be taken into consideration, however, before just judgment can be passed. He is not an individual of the pioneering type, prepared to "rough it" in the wooden shanties of the traditional mining camp. Furthermore, work is not so scarce in Belgium that he need deprive himself of home comforts in order to earn his living. Consequently it was essential at the outset to attract labor by providing home attractions on a liberal scale. The Campine, before its transformation, had nothing to offer. To artists in search of the picturesque and to the sportsman with his gun it doubtless held many attractions, but the miner after his days' work demands diversion of another kind.

No doubt recruits from other countries could have been obtained on easier terms, but the colliery directors are anxious to employ as large a proportion as possible of Belgian workmen and to exclude especially the vagrant here-today-and-gone-tomorrow type. About 16 per cent of the miners in the Campine are foreigners, chiefly Poles, Czechoslovakians and Italians. This proportion is likely to increase with the growing labor demands of the mines. The Flemish population of the Limburg province is more inclined to farming than to mining, and the annual influx from the southern coal-field will hardly be sufficient to meet requirements.

But there is a younger generation that in time will

FIG. 4

### Street Scene, Winterslag

Broad, gracefully curved streets and avenues, bordered with trees and artistically lighted are characteristic of these mining towns. To such communities as these with permanent abodes the term often applied of late years to the settlements of a similar nature in this country, namely, "a mining camp" is a misnomer.

FIG. 5

**A Villa**

This picture shows a villa of a mine official, the home of a mining engineer, yet this building, as well as others of its kind is not set apart in some aristocratic secluded neighborhood but is placed among, and flanked upon either side by, the homes of miners. This is characteristic of Belgian mining towns.

inherit the land and supply all the labor that is necessary. As one of the engineers remarked with a wave of his hand over the extensive construction work in progress, "It is for the next generation we are building all this." It is to be hoped they will appreciate the enterprise and the foresight of the engineers who are working in the field today and laying such solid foundations for the benefit of those who are in future years to follow after them.

One word must be added in acknowledgement of the courtesy shown to the visitor by the mine managers and engineers of the Campine. To one of their own craft they are generous with their time and do not permit him to feel that he is trespassing upon it, nor to depart with any other impression than admiration of the engineering skill embodied in these colliery shafts and works, and pleasure in the hospitality which has enabled him to visit them.

## The Miner's Torch

### The Wife of the Boss Man

**C**HANGING conditions bring on new problems; sometimes these new problems are almost old problems before we realize their existence.

Automobiles have been in pretty general use around our mining camps now for about ten years. Fifteen years ago there might have been found an occasional auto in a mining camp, but generally speaking at that date an auto was almost a novelty to the average mining village. Five years later almost any camp with passable roads leading to nearby villages had fleets of them. The changes brought about in our home and family life during these ten years have been momentous and far-reaching but we are only just beginning to appreciate them. About ten years ago the son of one of my college chums was promoted from mining engineer to mine superintendent, and a few months later decided that his future was promising enough to justify matrimony. I should have said that he decided to embark on the "sea of matrimony" because that word picture describes his adventure so well; their little craft encountered many a terrifying storm and the end is not yet, although the last storms encountered have been mild.

Five years ago I learned of a similar case. A few months ago I learned of another. Back in the days when I was a newly wed newish superintendent I was acquainted with a number of young men who belonged in my classification, and neither I nor any of them ever were troubled with the terrifying storms encountered by these sons of my friends, so when I heard of the last adventure mentioned I decided to make a little investigation.

I found that most of the young mine superintendents

of the present day who have passed from college to engineering jobs and then up to superintendent's desks have gone back to the cities (just as they did in my day) in search of their former sweethearts for wives, and while these young superintendents have had little love for the cities after marriage their brides are not similarly inclined. The automobile makes it possible for brides to keep in touch with city acquaintances and trips can be made back and forth without benefit of husbands and if necessary even without their knowledge.

Young superintendents have many duties and interests at the mines but the young wives are not so fortunate; whenever time begins to drag wives are apt to recall that an automobile is standing idle and then things begin to happen.

Back in my young days wives may have found time hanging heavy on their hands but they had to grin and bear it, at least that is what they did do. Blame the automobile? No! Blame the fathers who have censured the son's wives without realizing that times have changed.

### Resistance of Entry to Air

The results of a study of the resistance of coal-mine entries to the flow of air, made by Interior Department investigators at the experimental mine of the Bureau of Mines near Pittsburgh, Pa., are given in Serial 2621, recently issued. The Bureau of Mines initiated an extensive research on coal-mine ventilation factors in 1922, large-scale tests being conducted in its experimental mine over a period of two years. A comprehensive report on this work is in course of preparation but the present report is only the first of a series and considers only entries in which there are no obstructions other than the natural roughness of the ribs, roof, and floor. In order to place the practical results before the mining fraternity immediately and in condensed form, the more important features of the investigation will be presented in a number of short papers.

# Too Much Guess Work in Mining to Suit McAuliffe

Head of Union Pacific Coal Co. Appeals for More Accurate Knowledge—Objects to Common Plan of Ventilating on Basis of Input per Man Without Proof That Air Does Its Full Job

PERHAPS the most apt criticism that is now being made of the coal industry is that, to an extent, possibly exceeding any other industry of similar magnitude and importance, it depends for its conduct altogether too much on "rule of thumb" and "tradition," rather than on proven practice and actual fact. There are yet too many chances taken—we are still "weighing pounds on railroad track scales" and measuring yards with the proverbial "bit of string." The actual expense of conducting any one of the several operations incident to the production of coal is rarely determined, and in many instances the general cost figures, prepared some weeks after the work is complete, are of such a sweeping character that little can be abstracted therefrom. Many coal companies are now making a daily cost sheet, showing the cost of labor and material in detail, as used in the several related operations. This is quite helpful, particularly to the mine superintendent and his foreman, who, without it, sail an uncharted sea. The auditor's belated monthly summaries are rarely ever seen by these men who are held responsible for the labor and material used. I have made reference to this situation to accentuate the fact that the coal industry contains more "serious-minded, conscientious guessers" than does any other similar industry, although the annual cost of our product runs up well beyond the billion-dollar mark.

Now this brings me to the question of safety, the one question that should be, and which is, I know, uppermost in your minds. The coal-mining world, engineering and operating, is now well "sold" on at least two things—the theory of using permissible explosives and the elimination of the open light. Furthermore, the industry, particularly that portion which is located in the United States and Canada, is now planning vast extensions of the use of rock or shale dust, both in the form of dust barriers and in direct application to entries and crosscuts.

This is well. However, my study of past mine explosions has convinced me that the great majority of such blasts had their beginning in gas accumulations; frequently originating in restricted areas at the working face, in abandoned worked-out areas, or in some other place where ventilation is not maintained as it should be. And that again leads me to the point where it can again be well said, that there is too much rule of thumb, too much guessing now being done in regard to the volume of air required and continuously furnished, in a given entry, panel, room or area.

Just to emphasize this situation, is it not a fact that the majority of mine inspectors express the ventilation conditions as measured by them, in terms of cu.ft. per man employed, in each certain split, and do not the mining laws of many states yet demand a minimum of 100 or 150 cu.ft. per man, and 500 cu.ft. per minute for each mule, which is even worse than guessing distance?

By what process of reasoning can the relative freedom from gas in a given area be determined by the number of men employed? Five thousand cu.ft. of air, with one man employed, gives 5,000 cu.ft. per man. If 50 men are employed the result is 100 cu.ft. per man, the lawful minimum in certain states. This sounds insufficient but, as a matter of fact, the circulation created by the activities of 50 men adds to safety. This formula is a hoary survivor of the now obsolete, smoky, air-defiling oil lamp.

Again examine the average state mine inspector's annual report. You will find therein frequent reference to the size, type and drive of the fan used at a given mine and the cu.ft. of air handled, with water gage shown. However, the real question is, Does air reach every portion of the mine, does it scour the fresh working face and the shifting top in the pillar-drawing area, or does it, finding the line of least resistance, bypass through leaky stoppings, the circulation growing weaker, weaker, weaker, as it approaches the real gas-making territory?

Do you know you have air at the face? Have you a ventilation map of your mines, and do you get a regular and definite record of air at the face, or do you still use the rule of thumb?

Perhaps a simple illustration of what mine ventilation really means will be impressive. Take, for example, a mine producing 250,000 tons of coal annually, the average input of the mine fan 100,000 cu.ft. per minute, or 52,560,000,000 cu.ft. per year. We will disregard water gage, relative humidity and other factors in our calculations, dealing with weight alone.

The mean weight of air at temperatures ranging from zero to 95 deg. F. approximates 0.0774 lb. per cu.ft., therefore the weight of air forced through this given mine in a year totals 2,034,072 tons, equal to 8.14 tons of air to each ton of coal hoisted.

Perhaps a simple computation of the volume of explosive gas (methane or  $\text{CH}_4$ ), that is generated in an average mine may be equally illuminating. Let us assume the measure of air input given in the foregoing example, where the fan handles 100,000 cu.ft. of air per minute, equivalent to 144,000,000 cu.ft. in each 24 hours. Again assuming an analysis of the return air shows a gas content of one per cent, we find that

Eugene McAuliffe

NOTE—From a paper read by Eugene McAuliffe, president Union Pacific Coal Co., before the summer meeting of the Rocky Mountain Coal Mining Institute, Rock Springs, Wyo., Aug. 8.

1,440,000 cu.ft. of gas is generated in the mine daily, a volume equal to the capacity of 450 standard 40-ft. railroad box cars, filled to the roof. As methane weighs approximately 0.0451 lb. per cu.ft., the day's outpouring of gas would weigh 32.47 tons.

You will bear in mind that this volume of gas is harmless when diluted in the proportion of one to ninety-nine, but as gas weighs only about 55 per cent of the weight of air its disposition is to rise to the top, unless the scouring action of an adequate ventilation current sweeps it out of the places where it tends to gather, reducing it by diffusion to a harmless quantity. The foregoing presentation of the magnitude of the ventilation problem may or may not be useful to you; doubtless many of you have properly weighed the job in times past. It might be well to size it up anew.

Certain of our friends, whose mines are located in districts where much water must be handled, stress the millions of ft.-lb. of energy required to keep their mines dry. Keeping them aired is an even greater and more important problem; you see the water, it asserts its presence when neglected, but air, or lack of air, is a more insidious, secretive enemy; it hides its fangs until the moment comes to strike and then it strikes hard.

All mine foremen know what bad track, poorly maintained, without proper surface and alignment, short turnouts, etc., means to their haulage. By it the mine operations are slowed down, the output decreases, costs run up. So it is with air, it also requires a proper traveling way; one reasonably free from short curves, abrupt elbows, falls or other restrictions.

Again, the airway is a pipe, it must be tight or the contents will leak away before it reaches its destination. There is much in common between the natural laws that govern the movement of mine cars, of water in pipes and of air, through air courses. These laws are simple, but they are immutable; ignore them, neglect them, and you pay the price.

Reverting to the question of rock dusting: we propose to complete a most extensive program in our Wyoming mines, one which has been under way for some months, but our men are, I hope, all sold to the theory of air, air at the face, the whole face, and that continuously for each of the twenty-four hours in the day.

That means a dependent fan drive, automatic restarters on fan motors where electrically driven; it means adequate aircourses, kept clean; tight stoppings with overcasts instead of doors, and an ever vigilant policeman in the form of a recording water-pressure gage on every fan, with a positive inspection of the fan chart by the mine manager before the man trip is allowed to enter the mine each morning, and that regardless of the number of gas men employed or the fact that they have just reported, "Mine clear." These charts thereafter are scrutinized by the resident mine superintendent, the general manager, the general superintendent and the safety engineer.

In conclusion, I have two broad appeals to make. One is for the education, development and encouragement of the underground mine supervisory forces who stand nearest to safety and economical operation. These men deserve more encouragement and help than is now given them; many of them need to be shown how to help themselves.

My second appeal is directed toward a better relationship with the working force. We take too much for granted there. The great majority of men wish to and will do the fair thing, but perhaps they are not met half way by the employers.

The coal industry has for too long been the football of a careless, speculatively inclined attitude of mind. It is a great, vital, pulsating industry, where nature and man should combine to get better results. The industry's digestive tract is now being taxed to assimilate the excess mines and man power taken in during the frenzied war and post-war period. It has suffered from too much hysteria on the part of both capital and labor in the past. A permanent sense of composure will prove a Godsend to those who depend upon it for fuel; to the men employed within it, and I might also add, to the wives and families of the mine workers, who have in the past taken too much punishment.

The extension of the theory of local chapters of this and similar institutes, with frequent meetings, every man employed invited and urged to attend and to take part, will definitely help toward the solution of the problems that now beset the industry and its people. They will help coal-mining men to *know* their work. The poet Tennyson said, "Better fifty years of Europe than a cycle of Cathay." Let our motto be, "Better one proven fact than a dozen guesses."

### GAS BY THE CARLOAD

**EUGENE McAULIFFE**, with his well-known faculty of making ideas stick in men's minds, figures out that in a coal mine producing 250,000 tons a year and with an input of 100,000 cu.ft. of air per minute, the fans drive in 8.14 tons of air for every ton of coal hoisted. If this makes one per cent of gas in the return air, there would be 1,440,000 cu.ft. of gas removed from the mine in 24 hours. This is a volume equal to the capacity of 450 standard 40-ft. box cars. With thoughts like this in mind perhaps the average mine operator will better realize how important it is that his mine ventilation be complete and that he should know the air is doing its work and not merely *guess* at it.

Who Says There is No Beauty in a Coal Mine?

These "stalactites" and "stalagmites" appear each winter in the main slope of the mine at Scofield, Utah, formerly operated by the Union Pacific Coal Co. These manifestations of winter can be seen also in eastern mines. They constitute one of the difficulties of the mine superintendent. But rarely is the scene so picturesque as this.

# Rocky Mountain Institute Lays Down Safety Code

Coal-Mining Authorities of Colorado, New Mexico, Utah and Wyoming Believe in More Observance Rather Than in More Law—Declare for Rock Dusting and Sprinkling—Want Constant Educational Campaign

**T**O DO ITS BIT for coal-mine safety, the Rocky Mountain Coal Mining Institute, at its Rock Springs, Wyo., meeting, Aug. 7-9, adopted unanimously a long safety report over which the Institute's safety committee had been working for a year. The committee, which consisted of G. B. Pryde, W. Littlejohn, D. Harrington, W. W. Risdon, J. Dalrymple, Glen Knox and P. F. Patterson, recognized that conditions vary from region to region and that therefore it is not possible to lay down one set of iron-clad rules. However, the committee declared for rock dusting and sprinkling in mines where there is both fine coal dust and methane.

The Institute believes there is less need for more state safety legislation than there is for closer observance of existing law. "Betterment of safety conditions in coal mines cannot be materially improved by extraneous influence or intervention," says the report, "but must come from within the industry itself by those who are familiar with its conditions."

"We believe," reads the report, "that the propagation of safer practices in coal mining work will not be accomplished by laws if there is not the will nor the desire to obey them, but must ultimately be accomplished through education of the officials and the employees. The underground officials and particularly the mine foremen, on whom so much depends in coal mining, must be educated to recognize their responsibility and opportunity to spread the gospel of safety among the employees."

"The very fact that the mine foreman has been certified by the state as one capable of managing a mine and taking care of the safety of the employees under his charge should make him sensible of his responsibility and develop in him habits of patience, courtesy and persistency in all his relations with employees under his charge, and it will also be necessary to teach the employees that these rules and regulations are not designed to harass or circumscribe them in their daily work but have been developed for their safety and protection and for their personal welfare. When this has been accomplished a better understanding will have been reached and we may then look for a reduction in the accidents in and around coal mines. The following rules and regulations are submitted for your consideration and approval:

"(1) The mine foreman or someone who is in direct supervision of the workings should see that timbers

are set properly and that dangerous places are made safe. Such places should not be left until the employee has been properly instructed how to take care of them.

"(2) There should be a closer inspection and patrol of working places, to prevent accidents from falls of coal and rock.

"(3) On all main haulageways a space of at least 30 in. should be left between rib and track, or timber and track, and in all rooms not less than 2 ft. should be left between the track and upright timbers.

"(4) Each mine should adopt a definite system of timbering of haulageways and working places, applicable to its particular conditions or seam.

"(5) Seeing that many accidents are caused by cars running away in rooms where "wild catting," McGinty or snubbing ropes are used and that this can be overcome by the panel method of working pitching beds, which eliminates the handling of cars by the miner on these grades, all rooms should parallel the strike and not the pitch.

"(6) Shooting off the solid should be abolished wherever possible.

"(7) Black powder should not be used in any mine where coal is undercut, overcut or sheared.

"(8) When practicable no shots should be fired when any men are in the mine. This can be avoided by electrical shooting from the surface. In any event, no shots should be fired until all persons except designated shotfirers have left the mine.

"(9) Shotfirers should be highly paid, experienced, conservative men, should have plenty of time to do their work well, should have a thorough knowledge of explosives, of gas, of dust, and of electricity, and should be required to have a certificate of competency after passing an examination covering these subjects, the certificates expiring at least every five years and being renewable only upon passing another examination.

"(10) All mines showing gas in any quantities should be termed gaseous mines, and approved electric safety lamps should be used in them.

"(11) Shotfirers should see that all shots are properly placed, and should have authority to reject all holes that in their judgment are misplaced. Your committee would recommend the encouragement of a system of drilling, tamping and shooting of all holes, by competent shotfirers.

"(12) Wherever water is available, sprinkling lines

## ELECTRIC ARCS DANGEROUS ANYWHERE

**T**OO few people seem to realize the dangers of electric arcs in coal mines, the Rocky Mountain Coal Mining Institute believes. In its safety report, adopted at Rock Springs, it holds that all possible precaution should be taken against such flashes in mines both gaseous and non-gaseous. It was reported that two recent explosions occurred from electricity arcing into dust on main intake air courses, and that methane had practically no part in the resultant blasts which killed more than 200 men. In an outdoor demonstration at the time of the institute meeting the Bureau of Mines showed how likely transformers are to flash over when overheated, thus driving home the need for fireproof enclosures for all transformers underground.

should be installed and machine cuttings thoroughly wetted down. When practicable cutting machines should be equipped with water sprays on the entering side of the cutter chain. This is the safest way known to render dust inexplusive. When not possible to use water on cutter bars, it is essential that all machine cuttings be loaded out before shooting the working faces.

"(13) Mining machines should be used wherever possible as they have a tendency to decrease both major and minor accidents.

"(14) Employees should wear heavy shoes with a good stiff sole, as many accidents happen from the wearing of light shoes.

"(15) As many head injuries occur in mines, heavier caps should be worn; stiff fiber caps have been found to make excellent substitutes for the present caps worn by miners.

"(16) Whenever it is necessary to do so, trolley wires wherever men are working ought to be protected by two strips of wood, old hose, or canvas securely clamped to the wire. Accidents frequently happen from the neck or back of the head coming in contact with a live wire when repairs are being made near these wires. To prevent this, a piece of rubber or other nonconducting material should be fastened to the cap and extend to the shoulders. This should be detachable and worn only when the man is engaged in a hazardous occupation of the kind described.

"(17) Though dust alone furnishes the starting material for probably less than 20 per cent of our coal-mine explosions, it propagates nearly all of them and is probably responsible for much more than two-thirds of the loss of life.

"(18) Open lights have been the igniting cause of well over 50 per cent of our explosions; methane generally being the fuel, though under certain conditions coal dust can be ignited by the flame of a carbide lamp. Gaseous mines should be equipped with approved types of electric cap lamps.

"(19) Flame safety lamps, chiefly in the hands of firebosses or safety men, have caused several explosions with heavy loss of life; usually the lamps have been improperly assembled or otherwise have been misused. Before lamps are distributed they should be carefully inspected by a competent man. All lamps should bear the approval of the U. S. Bureau of Mines and should be magnetically locked before being issued.

"(20) All electric lines should be properly constructed and supported. Sectional circuit breakers should be installed every 2,000 ft.

"(21) Mine fires have been the source of several explosions, usually through interruption or reversal of ventilation and passage of methane into the fire region; consequently open lights should never be used in fighting mine fires.

"(22) As methane starts most of our explosions, all available precaution should be taken against its accumulation, a few being mentioned herewith:

"(A) Every mine should have mechanical ventilation, and if the mine is distinctly gaseous and employs any large number of men, it should have two fans or at least two distinct sources of power for driving the fan.

"(B) Mine fans should be operated 24 hours each day especially if the mine 'makes' gas.

"(C) Stoppings should be of tight and of durable material.

"(D) Where gas is generated at the working face, line brattices should be used from the last crosscut to the face.

"(E) Every large mine should have more than one air split; each split should be absolutely separate from all others, and each should have adequate volume of air to supply enough circulation at the faces to remove methane as it is emitted.

"(F) The mine should be ventilated without the use of many doors, and the doors necessary should be in pairs with an air lock between. They should be solid, tight and equipped to close automatically. All persons should be made to understand that doors must be kept closed as much as possible.

"(G) Where possible, workings should be in panels so as to confine the fire or explosion, if possible, to the panel in which it starts.

"(H) The ventilation should be under the direct supervision of some 'live-wire,' up-to-the-minute man, preferably with fair education and some technical training, and with much underground experience.

"(I) The driving of crosscuts in either entry or rooms, should be given the preference over the driving of either rooms or entries.

"(23) Coal dust seems to be explosive in proportion to its dryness and fineness and in proportion to the relation of volatile matter to volatile matter plus fixed carbon, the higher this quantity, the more dangerous the dust. Anthracite dust seems to be practically non-

#### On a Safe Slope

explosive, whereas bituminous or lignitic dust may explode even when the moisture or ash is above 25 per cent and may propagate any explosion when incombustible matter (ash plus moisture) is over 60 per cent. A slight quantity of methane (1 per cent or over) in the air makes dust more explosive. Less than one pound of fine, dry, bituminous or lignitic dust per lineal foot of entry will propagate an explosion with violence. Dust larger than 20-mesh is thought not to enter into explosions, but dust of about 100-mesh is dangerous and if of 200-mesh or finer constitutes an extreme hazard. Much of the settled dust on rib ledges is finer than 300-mesh.

"(24) The formation of dust is prevented to a certain extent by the use of longwall instead of room-and-pillar mining, by use of more holes and less explosive per hole in blasting, by use of the hydraulic cartridge or some similar method of bringing down coal.

"(25) Strong ventilating currents may remove dangerous dust from working faces, but such currents rarely are found at the face. On the other hand, strong currents of dry air tend to abstract moisture from the coal, making the dust the more dangerous. Dust removed from moving cars by strong air currents later settles on mine surfaces, constituting a definite hazard. Where water is available, water sprays should be placed at convenient points so that loaded cars may be sprayed as they leave the branch entries.

"(26) Humidification of intake air by steam, etc., rarely adds moisture to mine dust but it does have the helpful effect of preventing dry intake air from abstracting moisture from mine dust. However, the large investment required to provide the requisite volume of steam will probably prevent the general adoption of humidification by this method.

"(27) Sprinkling of roadways with the water car is not effective as it does not touch the dry, fine, settled dust on timbers or rib ledges, this dust being the most dangerous found in mines. By means of a small centrifugal pump, mounted on a truck adjacent to the water tank water can be delivered under such a heavy pressure that the roof and ribs are wetted thoroughly.

"(28) If a hose is used continually and systematically to wash down the roof, timbers and ribs and to wet the floor of all adjacent workings, the wetting being done by men who have no other duties, it, in our opinion, will be safe and effective if the water lines are kept at or near the coal faces and hose is available to keep the face wet.

"(29) A sprinkling system as above described, cannot be used on intake aircourses where winters are cold, except where preheating is done, and can be used only at great expense for timbering, etc., where roof, rib or floor material would be badly affected by water.

"(30) Rock dusting is preferred by many explosion experts to sprinkling as a preventive of explosions. The rock dust cools the flame and quenches it whether the explosion is one of dust or of methane. Moreover, if sufficient rock dust is present, it will prevent ignition of coal dust. Rock dusting is compulsory in certain classes of coal mines in Great Britain.

"(31) The rock dust should be 100-mesh or finer; should have little or no combustible matter; should have little or no free silica, as that material endangers the health of those breathing it; should not absorb moisture, and should not tend to pack or harden when left standing.

"(32) Rock dust should be placed on the ribs, timbers, roof and floor of haulage and working places by hand or by machine, and rock dusting should be repeated when the percentage of incombustible in rib or road dust falls below the required quantity to make the dust non-ignitable. This percentage is generally about 60 but may be as high as 75 to 80 if the coal dust is very fine or very high in volatile matter, or if there is one or more per cent of methane in the air. The rib and road dust should be sampled and analyzed whenever it is suspected that the coal-dust percentage is getting high. Dust should be removed from the mine at intervals.

"(33) Rock dusting of ribs, roof and floor, as above described, should be supplemented by placing rock-dust barriers the purpose of which is to confine or limit an explosion which might get a start. At least a half dozen of these barriers should be placed in series in each location, and should be made in accordance with recommendations contained in Bureau of Mines Bulletins 20, 26, 56, and 167. Improperly constructed barriers are useless, but well-constructed and well-placed barriers have quickly stopped violent explosions.

"(34) Any mine owner having dangerous dust or wishing to know whether his dust is dangerous should get in touch with the U. S. Bureau of Mines through the Director, engineers of that bureau having made detailed study of coal-dust problems. Any mine official also contemplating the use of rock dust should get in communication with Bureau of Mines.

"(35) In our opinion mines having dangerous dust with or without methane should both use rock dust and sprinkle the workings with water, the mines being sprinkled as previously described, but where water injures roof, ribs, or floor, or where water is not available, or where the workings are so cold that water freezes, the ribs, roof and floor should be covered with rock dust and dust should be placed on well-constructed rock-dust barriers at the entrance of panels or long entries. Even where only a sprinkling system is provided, the barriers should be used, but they should be in a series of six or more at each location and should

# SOME MINES NEED 80 PER CENT ROCK DUST

THE Rocky Mountain Coal Mining Institute is by no means satisfied that the commonly accepted "safe" proportion of 55 per cent inert matter in coal dust renders that dust non-combustible. It is all too familiar with the highly inflammable, resinous and volatile Utah coal dust. Therefore, it declared, in the safety report it adopted Aug. 8, that the proportion of inert matter in mine dust should be 60 per cent in any mine where any reliance is placed upon rock dusting and 75 or 80 per cent where the coal dust is very fine and highly volatile. The institute is so impressed with the dangers of coal dust that it recommends not only complete rock dusting, including the use of properly constructed barriers but also careful sprinkling in mines making methane.

**Car Designed for Safe Transport of Hay**

Going the Institute safety code one better, the Union Pacific Coal Co. is safe even to the handling of its mule and horse feed. This hay car has both a top lid and a rear drop door to prevent chance sparks from dropping in and to prevent spillage en route.

be constructed and maintained in accordance with instructions in Bureau of Mines' Bulletins.

"(36) No electric equipment should be placed underground except that of permissible type where such is available. Wherever permissible equipment is installed, a definite and complete system of inspection should be instituted, to insure equipment remaining in a permissible condition.

"(37) All possible precautions should be taken against occurrence of electric arcs in coal mines whether gaseous or non-gaseous.

"(38) The fireboss should not be assigned any larger district than he can properly cover in three hours without undue hurry, and the latter part of his shift should be confined to his inspection duties. Any official showing signs of carelessness in enforcing the state mining laws should have his certificate revoked.

"(39) Safety inspection of all mines should be made at least annually by competent outside mining men, preferably a safety engineer, and where feasible, this might be attained by annual temporary exchange of inspectors between the companies operating in different coal fields in order to obtain benefit of an interchange of ideas. We believe the suggestion regarding the exchange of inspectors to be practical and would recommend its general use.

"(40) Where a local safety man is employed continu-

ously, his reports should be made direct to the highest officials of the company and copies furnished to local officials. Local safety men should preferably be young, vigorous engineers of experience able to explore all workings and capable of reading and interpreting up-to-date technical articles on coal mining.

"(41) All underground officials should be required to carry a copy of the state mining law and to be familiar with its contents, and there should be posted in conspicuous places near every working mine, printed cards covering the provisions of the state mining laws concerning mine safety and also giving definite instructions to all workers about mines as to safety practices.

"(42) Miners rarely have any adequate idea as to what constitutes safety in coal mines, and this applies almost equally to the experienced miner and to the man who has worked in mines only a few months or a few years. To remedy this condition, an extensive campaign of education of miners should be instituted, and in this the mining companies should participate, getting aid from state and federal governments.

The mining companies should issue bulletins and letters on safety subjects, possibly have meetings at which safety is discussed or have local or outside speakers familiar with mine safety address the mine workers, or have moving pictures with safety subjects illustrated.

The state and federal governments should have well-informed, conservative mining men available to go among miners to talk safety to them or to issue pamphlets descriptive in simple language of safety practices and methods in mining.

"(43) All ventilating fans should be equipped with pressure recording gages and mine foremen should examine them to determine whether ventilation conditions are normal before allowing men to enter the mine.

"(44) Safety signs calling attention to specific dangers should be posted in several languages at conspicuous places throughout the mine and kept in such condition that they may be easily read.

"(45) Underground stations housing pumps, hoists, motor-generator sets, transformers or similar equipment, should be thoroughly fireproofed, using concrete, gunite or similar material."

#### **Protected Against Fire**

Motor - generator set in Mine No. 1 of the Union Pacific Coal Co. at Reliance, Wyo. Not a stick of wood or other flammable material is used in this rock-and-concrete room. The doors are flame-proof, making the whole a reasonably safe place.

Springfield High School Radio Club

## School Boys Work Out New Radio System for Mines

Springfield, Ill., Club Transmits Voice Vertically Through Ground—Scheme May Be Great Aid in Rescue Work—Previous Radio Communication With Mines Needed Metallic Conduction

BY A. B. McCALL\*

Springfield, Illinois

A. B. McCall

INTEREST has been aroused by the successful experiments of the Springfield High School Radio Club in underground communication between the surface and the interior of a mine, where 250 ft. of soil and rock intervened; not that such communication was unprecedented, for some previous attempts had been successful, but in every previous case dependence at such depths had been placed on con-

duction by wires, pipes and rails. In this instance there was direct, vertical transmission, using only the ground as a conductor.

The experiments were made at the Woodside mine of the Peabody Coal Co., at the edge of the city of Spring-

field, Ill. It was the culmination of much enthusiastic experimentation by the Springfield High School Radio Club, which had been working for many months with the technical advice of Frederick C. Holtz, an electrical engineer, and under my direction.

Thus it was demonstrated that it is possible to talk through the ground to men in a mine no matter if every entry is blasted shut by an explosion and every wire or pipe or rail line so badly broken as to be worthless as an aid to radio communication. Something new had been done for the mining industry and the men in it—something that may prove of great value in the mine rescue work of the future.

The radio club succeeded in its attempt while it was making official tests for the U. S. Bureau of Mines. It had won recognition by the government as an official experimental agency co-operating with the bureau in mine radio because its work in conduction of T.P.S. signals and voice between mine interiors and the surface had been so efficient and because its reports had been so intelligent and comprehensive that they were considered valuable fundamental data for the bureau's information.

The bureau several years ago undertook a series of investigations along this line in order to determine a simple and practical design of apparatus which might

\*Instructor in mechanical drawing at the Springfield high school and faculty advisor for the high school radio club. Consulting engineer in radio for the U. S. Bureau of Mines.

be used for transmitting and receiving the human voice through the ground to and from deep mine interiors in cases of disasters where rescue work is in progress.

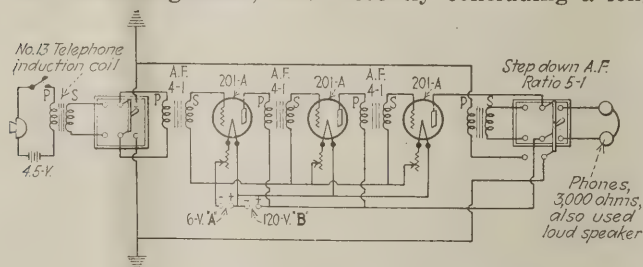

The popularity of radio and its many points of mechanical and electrical interest have led many people recently to undertake similar investigations and in consequence in the past year experiments of this character have been reported from many states in the union and many foreign countries.

The high school radio club of Springfield first achieved distinction in a series of experiments with radio in the nearby coal mines, where, in March, April, and May, 1923, it succeeded in sending and receiving both code signals and voice in and out of the mines from points a mile back in the mine interior and 250 ft. below the surface. Stories of its efforts in this connection were at that time published in a number of magazines and newspapers, and in the meantime reports of its experiments were submitted to the director of the U. S. Bureau of Mines by the president of the United Mine Workers of America, John L. Lewis, who personally volunteered an offer to co-operate with this club and the U. S. Bureau of Mines in any way that he could be of assistance.

It was then that the club won recognition from the bureau as an experimental agency. Following this recognition it was assigned the duty of gathering fundamental data concerning the conductivity of the soil and substrata lying between the coal seams and the surface in Illinois. When this assignment was made the club was lent experimental apparatus known as the T.P.S., or ground-telegraph, code transmitting and receiving sets.

The club completed a series of experiments with the apparatus lent by the Bureau of Mines, but while this was going on, the Club's experimental committee was quietly and systematically attempting to work out a plan to transmit the voice by ground conduction.

A series of investigations into mine radio conducted by the U. S. Bureau of Mines and other experimental agencies have, up to the present time, convinced engineers working on this problem that radio will be of limited usefulness for communicating underground in mine rescue operations. Some of the conclusions of the bureau engineers, after recently concluding a long

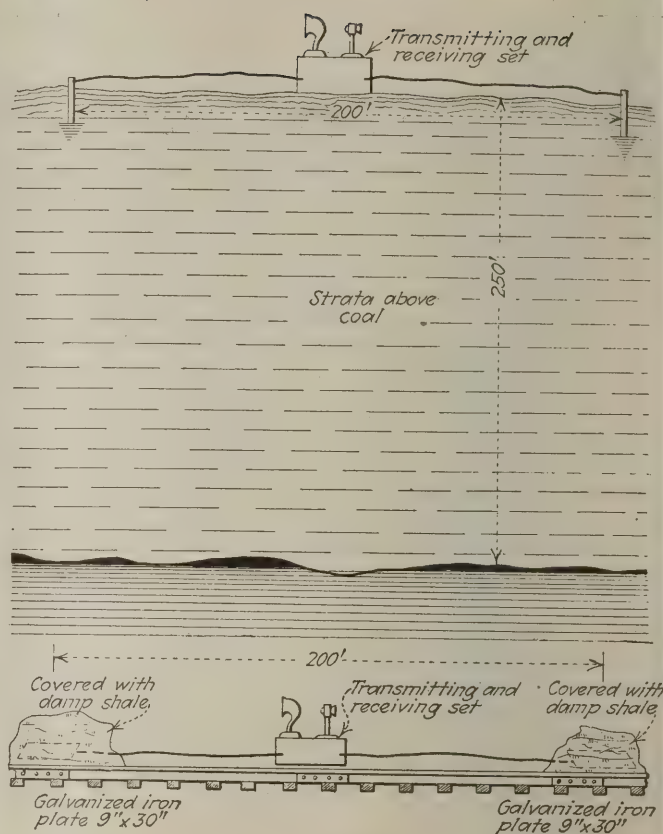

**Circuit by Which Surface Spoke to Mine**

This diagram shows the circuit used successfully, at Springfield, Ill., to exchange conversation vertically through the earth by ground conduction. No difficulty was experienced in conversing through 250 ft. of solid strata.

series of tests with radio in the mines about Pittsburgh, are, in effect, as follows:

First, radio waves will not penetrate through a sufficient thickness of earth strata to make radio practical for mine-rescue work without the aid of metallic conductors of some kind to act as a guide to the electromagnetic carrier waves.

Second, successes with radio even with metallic conductors, would be limited to the conducting qualities of

**Section Shows Position of Surface and Mine Sets**

The relation of the mine entrance to the surface station and the rescue station is immaterial as the currents pass through the solid strata and not through conducting media in the mine roadways. This shows the arrangement at the Woodside mine on April 27 when the successful experiment was made.

the metallic conductors, such as trolley wires, light circuits, telephone circuits, water pipes and mine-car rails.

Third, in the event of a cave-in or a mine explosion there is a great probability that the metallic conductors would get broken and perhaps grounded. This would reduce or destroy their ability to aid in communication with the underground workings just at a time when communication from the mine interior to the outside world might be most needed.

Realizing all these limitations the Springfield High School Radio Club attempted to find ways to overcome them and to devise a practical means of transmitting and receiving voice currents by ground telephony.

In this connection it will be evident that any method of communication for mine-rescue work will naturally have certain limitations, but the one big question to be considered is: Do those limitations make the system impossible for emergency use in mine rescue?

Of course, any method of communication with voice that would be simple to operate and easy to take care of should be as free as possible from interference from the natural elements, and anyone who has had any experience with radio is aware of the fact that in order to get any results with it, either in sending or receiving, not only does the operator have to learn to tune the apparatus but static and signal fading conditions tend to interfere occasionally and might do so at an unfortunate time for mine-rescue work.

As a result of the Bureau of Mines experiments, J. J. Jakosky has discovered some of these limitations of radio but he observed that as long as metallic conductors exist in the mine, radio communication between the surface and points several thousand feet back may be moderately successful even though small breaks may

occur in the conductors. Metallic conductors merely act as guides to the radio carrier wave which carries the voice so that small breaks may be jumped.

It has been repeatedly stated by men of mine experience that any set of apparatus used for mine-rescue work should not have to be tuned like radio, should have some means of eliminating static, should be simple to operate, should work with reasonable certainty and without difficulty in the event of an emergency and should not ignite gases. In this respect we can hardly feel as yet that radio alone will fill the bill.

With this information the radio club, after a series of discussions in meetings of its experimental committee tried out its system at the Woodside mine.

The test was successful. The students were subsequently informed by engineers of the Bureau of Mines that so far as available records disclosed, the club is the first experimental agency successfully to transmit and receive voice currents vertically to and from mine interiors using the ground as a conductor.

When all factors are considered, which enter into the ground conduction method of voice transmission, it will be readily observed that for simplicity, for dependability of service, and freedom from natural interfer-

A Flashlight of the Experimenters in Action

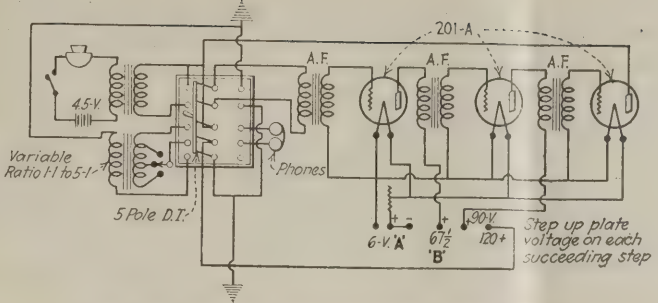

This group of radio club students actually heard the voices of those on the surface and talked with those above.

ences this system of underground communication may be expected to have many points of advantage over radio alone as a communicating medium.

For instance, this type of ground telephony, as will be noted in the circuit diagram, requires absolutely no tuning for success either in sending or receiving. It is further evident that the ground is likely to be a nearly constant conducting medium from month to month, especially if ground plates are buried to a reasonable depth below the surface soil to get away from the extremes of dampness and dryness.

The apparatus used by the radio club for vertical transmission of voice current consisted of a telephone transmitter with an induction coil with the line leads therefrom connected to the input of the first amplifier stage of a radio amplifying set. The voice current then passes through the desired number of stages of audio frequency amplification and passes out through the output connections and through a step-down audio frequency transformer (a 5-to-1 ratio being used with success) from which ground leads are taken by insulated wire to the ground electrodes which carry the voice current into the ground.

In permanent installations these ground electrodes preferably should be buried a few feet under the surface. Their distance apart depends upon the distance

More Compact Arrangement of the Circuit

This system, using three stages of amplification, has been devised for future experimentation.

that it is desired to send the voice currents through the ground, remembering that they can be sent practically from four to six times as far as the distance between the ground electrodes at the surface.

In the practical application of this system of underground communication it may reasonably be expected to operate successfully under conditions that have been suggested by mining engineers, mine owners and superintendents.

For instance, it should give good results in a mine having refuge chambers in each of several main divisions of the mine, a refuge chamber, for instance, in each of possibly four divisions, north, east, south and west.

An apparatus equipped for transmitting and receiving voice through the ground could be installed in each of the four refuge chambers, and there protected carefully from moisture accumulations. All battery terminals should be properly protected to avoid sparking. Each apparatus must have two ground electrodes connected by insulated wire to the set. These should be driven or buried in the roof or floor. Their distance apart should be equal to from one-fourth to three-fourths the depth of the mine, depending on the local conductivity of the sub-strata. The electrodes should be copper plates buried under damp loose shale or some such soil that is not too dry, or cemented in some manner securely within a slot in the roof to insure a good contact.

On the surface directly above each refuge chamber it would be practical to bury electrodes a similar distance apart, approximately 6 or 8 ft. beneath the soil and have them connected by insulated wire to a surface terminal housing as shown in an accompanying drawing. Such a housing would contain only the two terminal connections with the wires running to the buried electrodes.

It would then be practical for the mine office to be connected by relay or to have a portable apparatus which

Suggested Method of Housing Surface Terminals

The plates are sunk to a depth sufficient to assure that they will be in strata unaffected by the sun. It is important to have conditions standard, if possible so that no manipulation of the receiving instruments will be necessary.

in the event of an emergency could be rushed to the surface terminal above the refuge chamber, which houses the entombed men, and terminal connections made at once. A push button opens the circuit and a simple switch makes the change from transmitting to receiving. Miners entombed could easily talk to those at the surface set and vice-versa.

In the experiment conducted by this club, April 27, 1924, at the Woodside mine at Springfield, this is exactly what did happen, except that the experimenters below were not entombed.

This type of apparatus could save valuable time in case of disaster if the man leading the rescue party would station himself at a point near the rescue operations, bury the electrodes and with his set, weighing about 29 lb., communicate directly with the surface instead of using messengers.

**Ground Telephone Circuit in Simplest Form**

Here only one amplifying tube is used. Any good amplifying tube may be used for this purpose. On all the arrangements in these several illustrations patents are now pending.

## What Happens When a Coal Mine "Goes Up"?

**Bureau Men Show Crowd At Rock Springs, Igniting Dust Both by Electric Arc and Blown-out Shot—Transformer Smokes Too**

AT THE Wyoming state first-aid and mine-rescue meet, held at Rock Springs, Wyo., Aug. 9, the Bureau of Mines demonstrated effectively what happens when an electric arc or a blown-out shot ignites coal dust, and what does not happen when the coal dust has been rendered immune from explosion by admixture of rock

**Arcs and Coal Dust a Dangerous Combination**

This explosion, inside the gallery which had just been used in the Wyoming state rescue contest, proved that point to the crowd, a block away across Rock Springs First Aid Park, Aug. 9.

or adobe dust. Also, evidence was shown that a transformer should not be left unprotected in a mine.

The first act of the show was the ignition of coal dust by an electric arc. A long wooden gallery, that had been used for the rescue contests, served as the "mine." In it an electric arc was obtained by pulling a circuit breaker on average mine voltage. Twenty-five pounds of fine coal dust were blown over the arc made by the opening of the circuit breaker. The result was a great flash of smoke and flame as the coal dust exploded, simulating what happens when an arc occurs in an atmosphere containing coal dust in suspension. Water from a fire hose saved the gallery for the rest of the show.

Next, the arc was pulled just after another 25 lb. of dust had been blown into suspension within the gallery; but in this case the result was different. The dust was 60 per cent adobe and only 40 per cent coal. Nothing happened except a little flash of the arc and a rolling, but harmless cloud of dirt from the mouth of the gallery. The adobe had stopped the "mine explosion."

Meantime two 440-volt, 10-kw. transformers with their secondaries shorted in plain sight of the audience, heated up dangerously and emitted clouds of smoke from the boiling oil within them. However, the flash-over always likely in such cases, did not occur, but the mining men got the idea just the same. Transformers have dangers like most other electrical apparatus. They should be kept off the intake airways in mines and should be housed in flameproof stations with self-closing doors, and otherwise protected.

The finale was a whooping blast which blew the gallery to pieces and sent up a frightful cloud of flame and black smoke. It was a dust explosion caused by a "blown-out shot." The gallery was loaded with fine coal dust on rafters and shelves just as coal dust accumulates on roof and ribs in a mine entry. Then a cloud of it was blown into suspension just as a small cannon at one end of the gallery fired a spurt of flame. The result was satisfactory to everybody concerned. The gallery disappeared.

This picturesque demonstration to teach the lessons of mine safety, was the first of its kind ever held in the West.

**Wham! Up Goes The Whole "Mine"**

In this case, fine, dangerous coal dust was not only piled through the gallery just as it accumulates in a real mine entry, but 25 lb. were thrown into suspension. A little cannon fired the "blown-out shot." The instant after the picture was taken the gallery "went west." At this instant the end where the shot was fired was being blown to pieces and the air blast through the gallery had just begun to blow out the burlap curtain at the other end.

## News Of the Industry

### C. P. White Expected to Prove Big Asset To Government Coal Division

Broad Experience in the Industry Will Be Helpful in Building Up Export  
Business—Enjoys Full Confidence of the Trade—  
Assumes Duties This Week

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Under the immediate direction of C. P. White, the new head of the coal division of the Bureau of Foreign and Domestic Commerce, the great influence of the department and the use of its far-flung facilities are to be employed in an effort to be helpful to the American coal industry. As is known generally, Mr. White's circumstances are such that he can accept public service with only secondary regard for the salary. Because of that fact the department has added to its staff of commodity specialists a more capable man than ordinarily would be attracted by the government's idea of technical salaries.

Mr. White needs no introduction to the American coal trade. He has been associated with the coal business since he left high school. The fact that he has been called upon on a number of occasions to serve as a member of scale committees gives an indication of his detailed knowledge of the business. As a young man he was connected with the coal department of the Wheeling & Lake Erie R.R. Later he was connected with coal-dock operations at Superior, Wis. At one time in his career he was manager in the Northwest for the Pittsburgh Coal Co. He served the Carnegie Dock & Fuel Co. at another time in the same capacity. He has been prominently associated with the activities of the Pittsburgh Vein Operators Association. As general manager of the Clarkson Coal Mining Co. he acquired practical experience in the operating end of the business. His familiarity with the situation in the Northwest and in Canada resulted in his being chosen to direct that important distribution for the Fuel Administration. In similar fashion he was called upon to handle the Northwestern distribution when the federal government took a hand in the situation following the strike in 1922.

Because of his long association with the business and his wide acquaintance among the producers and distributors of coal, he undertakes his work with the important advantage of enjoying the full confidence of the industry. While he has some very concrete ideas as to the assistance which the department can extend to the coal

industry, he will recommend no program until he has conferred with the industry. He believes the suggestion as to the steps which would be most helpful just at this time should come from industry rather than from the coal division. At the same time Mr. White realizes that were he to sit in his office and wait for suggestions to come in a considerable portion of them would come from those who have axes to grind. To get a real cross-section of the more urgent needs of the business, Mr. White believes it will be necessary to obtain this information by personal contact when ideas can be drawn from a man who is too busy to write them in or who fears that his motive might be misinterpreted.

#### Government Activity Resented

In certain quarters there is a feeling of resentment aroused by any activity of the federal government which has to do with coal. This has its origin largely in the fear that the government will seek in some way or other, eventually if not now, to interfere with the normal conduct of the business. No such apprehension is justified in connection with the activities of the Department of Commerce, at least.

In the matter of increasing our exports of coal Mr. White entertains no dream of sudden expansion. While he realizes that we do not occupy an advantageous position to compete in the world's coal markets, nevertheless he thinks American genius for organization, backed by the country's capital resources, should find a way to increase our exports of coal. He points out in that connection, however, that progress in that direction will be slow and beset with many difficulties. Since much more is involved than the sending out of salesmen to take orders, Mr. White feels that there should be concentration on this problem by the best minds in the industry. He admits that our overseas coal trade cannot be increased greatly beyond its present dimensions without correlating this trade with other enterprises, which in most cases would involve large capital outlay.

While Mr. White's assumption of his duties at the Department of Commerce was the matter of immediate interest

### Besson Passes Test and Is Reappointed

Leon Besson, who was appointed state mine inspector of Kansas April 1 and removed on July 12, was restored to the position Aug. 18 after passing an examination for the post. An ouster suit was brought against Besson on the ground that he had not qualified by taking the inspector's examination before the state mining examining board. The court held that the inspector is required to take the examination. The Industrial Court, which appoints the inspector, then removed Besson and designated Ernest Shaw, deputy, to act as inspector. Besson took the examination Aug. 16, passed with a high rating, and his reappointment followed.

in Washington this week, there is another development which may take more definite form in the near future. Those who are directing the Republican campaign and those who are serving in a similar capacity under the banner of the Democratic party are much concerned over the discontent among mine workers who are out of employment. They fear that many of these men are likely to vote for Senator La Follette. The concern seems to be greater among the Democratic leaders. It is their impression that the loss of this vote will hurt their party more than the Republicans.

The Republicans, however, do not concede that a majority of these men are normally Democrats. They point to the fact that John L. Lewis is regarded as a leader in the Republican party. His name was discussed seriously in connection with the Vice-Presidential nomination. Many other leaders among the mine owners are known to be affiliated with the Republican party and it is contended that their political convictions are shared by many of the mine workers. However that may be, each of the old parties is very anxious to suggest something that will increase employment in coal mines. Some are of the opinion that the situation in such doubtful states as Indiana and Ohio might be helped materially were the United Mine Workers induced to accept a lower wage scale. It is known that such a suggestion would be spurned by the leaders of the mine workers, but some are of the opinion that the rank and file of the union might be influenced to bring enough pressure on them to cause them to call another conference.

## Home Trade Unsettled, British Producers Keen on Export Business

Nearness to Continent, Long-Established Connections, Large Supply of Ships and Low Freights, Says Hutchinson, Are Obstacles to American Headway in European Markets

Philadelphia, Pa., Aug. 26.—“The report made by the David Lloyd George committee, professing to be against the nationalization of British coal mines but recommending governmental ownership of the coal and the leasing of the mining rights, is generally regarded in England as a political document,” said S. Pemberton Hutchinson, president of the Westmoreland Coal Co. and also president of the National Coal Association, in an interview today. Mr. Hutchinson, with several members of his family, returned from a six weeks’ trip to Europe, having visited England, Wales and France. While abroad he took occasion to sound out mine owners and other business people on the British coal situation. Mr. Hutchinson’s statements on conditions in the British coal industry were elicited in response to a series of questions propounded to him, as follows:

What is the present condition of the British coal industry?

“The British coal situation is not good. The iron and steel trade in Great Britain is in a depressed condition, over one-half of the blast furnaces being closed down. This being a basic industry, its condition naturally is reflected in that of the coal industry. As a result of that condition there is a very light local demand for British coal. Thus the British colliery owners are giving special attention to the export business. Their nearness to the European market, their long-established connections, the large amount of ocean-going tonnage and low ocean rates all contribute to the strengthening of their export business and prevent, in my opinion, American coals from gaining much headway in European markets at this time.”

What effect will the general increase in wages under the recent settlement in England have upon the ability of the English coal operator to compete in the world’s markets?

“The new wage agreement has not been in operation a sufficient length of time to enable anyone to determine how it will work out. It is my belief, however, that it will have but little effect upon the export business. I think the English operators will strive to expand their export business, even though they make very little money out of it.”

What in your opinion will be the effect of the Ruhr settlement on the world’s coal markets?

“It ought to help the coal markets of the world, because it will make for commercial stability. It is believed that the adoption of the Dawes plan will result in a more prosperous and stabilized condition of all the nations of the world, thereby increasing the consumption of coal.”

What suggestions have you for furthering the American overseas coal export trade?

“I suggest that the American coal exporter can materially improve his standing in European markets if he will continue to advertise American coals abroad and send cargoes for introduction into the markets of the world, primarily with the view of establishing the coals rather than making much immediate profit on the transactions.”

How do the housing and living conditions of the British miner compare with those in this country?

“The housing and living conditions of the miners in Great Britain are by far worse than they are in the United States. This opinion is based on my own observations and is corroborated by statements and descriptions contained in the report of the Lloyd George committee.”

How is the report of the Lloyd George committee on the coal situation regarded by the industry?

“It is looked upon as a purely political document and its recommendations are opposed by both operators and miners.”

In a recent analysis of the British coal situation English coal distributors stated that the fundamental problem in the industry was regularity of demand and that all other problems would be corrected if demand were stabilized. Does this seem to be the general opinion among thinking people in Great Britain?

### Workable Stabilization Plan Lacking

“Yes; those who have studied this subject seem to be of one accord, but so far no one has been able to devise a plan of stabilization that is practicable or workable. It is my opinion that they will not be able to do so, because in order to stabilize the demand for coal it would be necessary to compel every user of coal to make his purchases at fixed times. This form of regulation would be contrary to sound economic laws and I do not believe it would ever be successful.”

The Miners’ Federation of Great Britain is advocating complete unionization of the mines and has taken steps to have a bill introduced into Parliament making membership in the federation a condition precedent to employment. Are the British coal-mine owners taking this proposition seriously?

“I do not think so. From my observations I would say that this is a political move, and apparently the mine owners do not anticipate the enactment of the bill.”

During the course of Mr. Hutchinson’s interview he took occasion to state that since his return from abroad he has become convinced that the coal trade in this country is on the upgrade, his belief being predicated on increasing inquiries about coal and future contracts, as well as increasing output.

### Coal Stock Report Sept. 1

After some effort, the Geological Survey and the Bureau of the Census have found money enough to take a coal stock report as of Sept. 1.

### Big Merger of Hard-Coal Independents Planned

The consolidation movement apparently is about to spread to the anthracite field, a special dispatch from Scranton, Pa., stating that another big hard-coal producing organization that is expected to be a competitor of such companies as the Hudson and Glen Alden is in process of formation. A group of independently operated collieries and mines are to be merged to form the new organization. All companies mentioned are large producers of anthracite.

A group of Pennsylvanians, among whom are mentioned Wm. C. Sproul, former Governor of the state, and Newton D. Jackson, of Philadelphia, are said to be promoting the enterprise. Among the independent coal companies which may be affected by the merger are the Temple Coal Co., the East Bear Ridge, the Scranton Coal Co., the Legitts Creek company and several smaller producers.

A definite move toward the consolidation was manifested clearly over the week-end with the visit to Scranton of former Governor Sproul, whose name has been linked with the promotion of such a merger for some time. A report that bears the weight of authority has it that the former Governor, while in Scranton, completed negotiations for the purchase of the Traders Coal Co., an independent producer, with offices in Scranton. It is known that Mr. Sproul was in consultation with officials of the Traders company.

For some time negotiations have been in progress to buy the coal properties with a view to merging them into one corporation with resources of capital and combined output sufficient to give the stock or bonds contemplated for issuance a high financial rating on the market.

### Farrell Coke Plant Closes as New Clairton Ovens Open

The Carnegie Steel Co. coke plant at Farrell, Pa., was closed Aug. 22, and it is likely that it will never be reopened. The three batteries consist of 212 ovens, but only 50 have been in operation, due to the idleness of two of the three blast furnaces. Whether the plant will be dismantled is not known.

The closing was brought about by the starting of the big byproduct plant of the company at Clairton, Pa. The latter is in position to ship both coke and coal tar for fuel to Farrell at low cost. For the present blast furnace No. 2 will be operated on stock coke.

Tar from the Clairton works also will be used for fuel in the open-hearth furnaces at Farrell.

For the first time since the open-hearth furnaces were built all of them will use coal tar.

## Coal Production on Competitive Basis Is Central Pennsylvania's Need

**Operators Decry Advantage in Low Production Costs Enjoyed by Non-Union Districts Because of Lower Wages—West Virginia Gaining Despite Depression in Union Districts**

"The most important matter discussed at the meeting of the coal operators held in Altoona, Pa., Aug. 22," according to a statement by Charles O'Neill, secretary of the Central Pennsylvania Coal Producers' Association, "was the business situation. The depression in the central Pennsylvania coal field is more acute than in other coal-producing fields. This is due, of course, to the high wage scale obtaining in the union districts. The non-union fields are working on greatly reduced wage scales and are taking the business. The wage scales in the non-union fields permit them to produce coal 50c. to \$1 per ton less than in the union district of central Pennsylvania.

"The number of idle mines in this district, and the working time of the others is as follows: Mines idle, 652; mines working 1 day, 79; mines working 2 days, 85; mines working 3 days, 74; mines working 4 days, 65; mines working 5 days, 44; mines working 6 days, 63.

"In order to offset the reply that non-union fields are having the same troubles today, due to the general business depression of the country, as the union fields are having, I wish to quote a few figures showing comparison between our district and the non-union fields of West Virginia, showing the cars of coal loaded in each section from Jan. 1, 1923, to July 19, 1923, as compared with the car loadings for the same period of 1924: Non-union, West Virginia, 686,154 in 1923, 759,294 in 1924; central Pennsylvania, 502,022 in 1923, 367,613 in 1924.

### West Virginia Catching Up

"The non-union mines of West Virginia gained in production this year 11 per cent. Central Pennsylvania has lost in production 27 per cent. These are the facts.

"The mine workers in their published statements rely upon the reports of the U. S. Geological Survey. These reports are accurate as to the mines that are in operation. They do not cover, for instance, the 652 idle mines in our district. The actual car loadings are the only real measure of one section against another.

"The miners' leaders agree to the proposition that there are 200,000 too many men in the industry and too many mines. The present policy means that the 200,000 men who must leave the industry must be union miners, and the invested capital in the excess mines to be wiped out must be the capital invested by union operators. High wage costs now have the union mines at a disadvantage of 50c. to \$1 per ton in cost as compared with their competitors.

"There is only one cure for the present situation. If prosperity is to return permanently to this section its basic industry, coal, must be put upon a competitive basis. The union miners,

if they propose to remain in the industry, must bear their share of the cost of the 'struggle for the survival of the fittest.'

"The serious questions involved in this issue were a matter of discussion at the meeting Aug. 22. It also will be a matter to be considered at the annual meeting of the operators to be held at Altoona on Sept. 5, 1924.

"The district officers at the miners' union assert that they are helpless in the matter, and that the present policy of supporting a high wage scale in the union fields and a low wage scale in the non-union fields is due to the international officers. In the meantime miners suffer, and operators and business men of this section face bankruptcy."

### Move to Prevent Denial of Civil Rights of Miners

As part of a movement launched to improve conditions and to "stop the denial of civil liberties" in the soft-coal fields the American Civil Liberties Union, 100 Fifth Avenue, New York City, has sent a circular letter to hundreds of attorneys, ministers and officials in the non-union soft-coal districts.

"The suggested action," says the announcement, "includes the incorporation of the company-owned coal town; a fight against the so-called 'yellow-dog' contracts under which miners are prevented from joining unions, and efforts to have deputy sheriffs and local law-enforcing officials paid entirely by the county instead of by private coal corporations. Suggestions also are made for contesting injunctions which deny miners the right to organize and hold meetings, to strike and to picket. The districts chiefly affected are western Pennsylvania, West Virginia, Alabama and Utah."

The U. S. Coal Commission is cited in the announcement as authority for the statement that the domination of those districts by the coal companies is responsible for the "practical abridgement of free travel, free speech and public assemblage," and for depriving miners of "their normal rights."

These findings, according to the Civil Liberties Union, "will go their way into the archives like other government reports unless somebody gets busy to put them into effect. That we conceive to be our job. We are opening a campaign in the non-union soft-coal districts which we trust will result in restoring those communities to the exercise of the ordinary civil rights of American citizens."

The Civil Liberties Union plans to organize committees in the districts affected to work for the Coal Commission's program, and to carry on an active agitation in the localities and the state legislatures.

## Atlantic Coast Line and L. & N. Approve Clinchfield Lease

Officials of the Atlantic Coast Line and the Louisville & Nashville R.R., following simultaneous meetings in New York City, announced Aug. 21 that they would go ahead with their plans for the acquisition by lease of the Carolina, Clinchfield & Ohio Ry., subject to the terms and conditions imposed by the Interstate Commerce Commission in its recent authorization order.

The conditions laid down by the commission included the following:

Applicants must maintain the Carolina, Clinchfield & Ohio as a separate corporate entity and shall maintain a separate organization for the combined properties of the company, with a responsible operating management directly in charge; existing routes and channels of trade heretofore established by other carriers in connection with the Clinchfield must be preserved; the applicants must permit the line of the Clinchfield and its subsidiaries to be used as a link for through traffic via existing gateways of interchange, or via gateways to be subsequently established under authority of the commission by means of connecting lines proposed to be built by the Louisville & Nashville.

The application of the Atlantic Coast Line and the Louisville & Nashville calls for a 999-year lease, and this term is approved by the commission, dating from May 11, 1923.

The lessors are called upon to file within six months with the commission an application to build connections between the McRoberts and Harlan lines of the Louisville & Nashville and the line of the Carolina, Clinchfield & Ohio.

### F. G. Hatton Takes Over Two Kentucky Mines

F. G. Hatton, president of Hatton, Brown & Co., Inc., Columbus, Ohio, announces that his company has taken over two large producing properties in the Betsey Layne field on the C. & O. R.R. in Kentucky. The properties were taken over by the Peerless Elkhorn Coal Co., a \$150,000 corporation, of which Mr. Hatton is president. The properties are the St. Paul Coal Co. and the Big Elkhorn Coal Co., with combined holdings of 900 acres and two operating mines. The output of 500 tons daily will soon be doubled and extensive improvements will be installed. The product will be marketed through the Hatton-Brown Co.

### Conference May Amend Scale In Pomeroy Bend Field

Arrangements have been made for a conference of operators' and miners' representatives which will be held at Minersville, Ohio, soon in an effort to arrange an amended wage scale for the Pomeroy Bend field. The conference will consist of all operators in the Pomeroy Bend field. Many of the mines of the district are idle and it is hoped that concessions in the cost of production can be obtained in order that some of the mines can operate.

## National Safety Council To Hold Its Annual Meet In Louisville, Kentucky

Expectations are that the Thirteenth Annual Safety Congress of the National Safety Council at the Hotels Brown and Seelbach, Louisville, Ky., Sept. 29 to Oct. 3, will be the best yet held. The first edition of the program has just been issued by headquarters at 168 Michigan Ave., Chicago. The opening session will be held Monday at 10 a.m. in the Hotel Brown with the president of the Louisville Safety Council, the mayor of the city and the president of the Chamber of Commerce of the United States among the speakers.

In the afternoon at 2 o'clock the Secretary of Labor will speak on the "Fundamentals of Our Industrial Safety Program," Dr. Arnold L. Jacoby, director, psychopathic clinic, Detroit, Mich., on "Mental Causes of Accidents," Jamie Heron, of Chicago, on "Building Men for Safety," and A. W. Whitney, chairman, American Engineering Standards Committee, on "Standardization of Safety Codes." A motion picture, the new industrial film of the National Safety Council, "A Word to the Wise" will then be presented.

### To Show Safety Developments

On Tuesday morning at 10 o'clock the Mining Section will hold its first session with the addresses of the officers, an address by E. E. Jones, electrical engineer, E. E. White Coal Co., Glen White, W. Va., on "Stray Electrical Currents, Their Dangers and Avoidance," C. L. Colburn, who has been travelling extensively, will deliver an address on "Safety Kinks," and W. W. Adams, U. S. Bureau of Mines, Washington, D. C., who has been collecting detailed statistics from members of the Mining Section, National Safety Council, will present summations of those statistics, giving no details, however, as to individual companies. On Tuesday afternoon C. E. Pettibone, vice-president and manager, Engineering Department, American Mutual Liability Insurance Co., Boston, Mass., will show one hundred new slides from photographs contributed by members of the National Safety Council, showing new outstanding developments in safeguarding.

At 10 o'clock on Wednesday morning N. S. Greensfelder, editor, *The Explosives Engineer*, Wilmington, Del. will discuss "The Safe Use of Explosives"; Francis Feehan, U. S. Bureau of Mines, Pittsburgh, Pa., will give an address on "Organizing the Mining Industry for Safety," and J. B. Johnston will follow with an address on "Safety in Underground Use of Electricity."

Thursday morning will see the third session of the mining section with G. F. MacWilliams, electrical engineer, Pennsylvania Coal & Coke Corporation, Cresson, Pa., discussing "Electrical Starting Apparatus from the Viewpoint of Safety"; and probably R. N. Hosler, superintendent Pennsylvania Compensation Rating & Inspection Bureau, "Schedule Rating for Compensation Insurance." This will be followed by a round table discussion.

### Unique War Memorial

Five-ton block of coal placed in front of the Lattimer (Pa.) office of Pardee Brothers & Co., Inc., as a memorial to the company's men who took part in the late war. It bears a tablet with the following inscription: "Memorial to the Employees of Pardee Bros. & Co., Inc., World War, 1917-1918." The enclosure is about 18 ft. square and the flagpole is 80 ft. high.

## Crossed Wires Cause Fire In Ohio Coal Mine

Special to Coal Age

Columbus, Ohio, Aug. 23.—Crossed wires in the Lincoln mine of the Lorain Coal & Dock Co., located near Bridgeport, Belmont County, Ohio, caused a fire late Aug. 22. A portion of the workings were closed up to stifle the flames and it will be a week or ten days before it can be opened and the loss definitely ascertained. In the meantime the loss in output will be about 500 tons daily, as it was one of the smaller operations of the company. It was not necessary for the mine rescue car to be called as there was no loss of life or injury to workers.

## Kansas Open-Shop Miners Join the Union

Employees of three open-shop mines near Scammon, Kan., accepted with alacrity an invitation delivered personally, Aug. 19, by more than 1,000 union miners, to cease work until they might be admitted to the United Mine Workers. The mines affected were the Mackie J., a co-operative mine, operated by twelve men and employing forty-five; Mayer No. 11, leased and operated by Overjohn Brothers and employing forty-two men, and the Stocker mine, operated by George Mertz and employing thirty-seven miners.

## Orient No. 2 Resumes Work

Orient Mine No. 2 of the Chicago, Wilmington & Franklin Coal Co., Herrin, Ill., has resumed operations, after having been idle since July 16. The strike was the result of a controversy between the company and men over the scale for undercutting machine men. Three hundred men are now at work.

## More Glen Alden Mines Close Because of Card Strikes

Special to Coal Age

Scranton, Pa., Aug. 27.—In an effort to impress upon the minds of alleged insurgent union leaders the futility of unauthorized, contract-breaking strikes at its collieries, the Glen Alden Coal Co. has evidently adopted a policy of closing down operations indefinitely after outlaw strikes have been put into effect by the men at the workings.

During the week the Hallstead colliery at Duryea, near here, employing 200 men, was shut down when the miners declared a strike after one of the employees refused to show his working card to a union official. After a day of idleness the men decided to return to work, but the company in the meantime had taken action. The fires were pulled and power shut off. Everything was placed in a condition for a long shutdown and the miners were told that the company had called off operations and the mine would remain closed for an indefinite period.

Similar action was taken at the Woodward colliery, at Edwardsville, about a month ago, with the result that the 1,800 men employed there have been on the idle list for more than four weeks and will continue to remain so for some time to come. Repairs are now being made at the Woodward colliery.

The frequency of outlaw strikes, it is understood, has resulted in this mode of procedure by the company officials.

## Wants Pittsburgh Rates Cut, Others Raised

Under the arrangement in the Lake Cargo coal case August Gutheim, on behalf of the Pittsburgh Coal Producers' Association and other complainants, has submitted to the Interstate Commerce Commission a digest of the testimony on which his argument, to be submitted later, will be based. In submitting the digest of the testimony to the commission, Mr. Gutheim makes the point that the Pittsburgh rate of \$1.66 should be reduced to \$1.26 and at the same time points out that the differential from the Fairmont, Kanawha, Thacker, New River and Pocahontas districts, the so-called preferred districts, should be increased, when due consideration is given the commercial and competitive situation. He presents evidence to the effect that Pittsburgh has lost some 40 per cent of its lake business, while the preferred districts have been gaining. In 1912, when the commission reduced the Pittsburgh from 88c. to 78c., it was pointed out that the latter rate still was too high when measured by the cost of service. At the same time the Norfolk & Western was authorized to increase its rate. The B. & O., the C. & O. and the New York Central, however, made no attempt to justify a rate increase, with the result that the Norfolk & Western could not apply it.

Since that time Pittsburgh rates have been increased 115 per cent, whereas the southern district rates have been increased only 90 per cent, thereby aggravating the situation still further.

## Herrin Mass Meeting Finds No Cure for Ills of Southern Illinois

**Union Men Fail to Attend and Operators Recount Handicaps Imposed by Inelastic Wage Scale—Miners Insist on Maintenance of Present Contract**

"Illinois mines are idle not because of a business depression or because coal substitutes are being used but because coal from other fields is going where Illinois coal formerly went," declared Dr. F. C. Honnold, secretary of the Illinois Coal Operators' Association, at a mass meeting held at Herrin, Ill., Aug. 20. "The output of the mines of Illinois has failed lamentably to show normal consecutive growth during the past dozen years."

The meeting was held under the auspices of the Lions Club in an effort to bring about the rehabilitation of mining in southern Illinois, which is suffering from all the economic ills that a general shutdown and unemployment in its main industry naturally would bring about. The coal operators and state officials of the United Mine Workers were invited to be present prepared to set forth all angles of the case. The union miners, who were held responsible for the present depression by both the coal operators and the railroad officials, failed to attend the conference, but in a letter made public just before the meeting reaffirmed their determination to maintain the present wage scale until its expiration in 1927.

### Faint Hope of Resumption Soon

The conference indicated that there were scant hopes of resumption on the part of the operators. Dr. Honnold and several operators with large mines in this vicinity declared that orders for Illinois coal were steadily declining and that even Chicago customers of long standing were finding it cheaper to pay the heavier freight rates on non-union coal from Kentucky and West Virginia than to buy southern Illinois coal mined under the scale ratified at Jacksonville. "So long as the present scale persists we will observe the scale, but our mines will have few orders," the operators said.

There is no reason to expect, Dr. Honnold declared, that the annual output of Illinois mines for the next five years will exceed 60,000,000 tons a year (the prewar output), in spite of the fact that the bituminous coal consumption of the country has increased 20 per cent since 1912. If Illinois kept pace with other fields she should average 80,000,000 tons a year. This condition holds in spite of the fact that one-sixth of the bituminous coal production of the country is consumed in Illinois.

### Handicapped By High Costs

"Today the mines of Illinois furnish less than half the coal requirements of the state because the cost and consequent price of Illinois coal is too high. More than 50 per cent of the daily production of bituminous coal in the United States is coming out of mines where it is produced at a cost only

slightly over half the cost of similarly circumstanced Illinois mines. Part of this lower cost at competing mines is due to lower wage scales, part of it is due to more favorable contract and working conditions under the wage agreement, and part is due to the rapidly increasing use of mechanical devices and changed methods of mining."

Non-union mines are operating on the wage scale of 1917, Dr. Honnold declared, while Illinois mines pay \$1.25 a ton above the 1917 scale, which was higher than that of the non-union fields. "That differential permits competitors to pay the heavier freight rates to the Chicago market and undersell Illinois coal," he said. "We will have difficulty in regaining those customers and because of our non-elastic agreement with the union we must continue the present scale for three years. The industry loses from \$10,000,000 to \$12,000,000 a year on screenings because of union restrictions—a burden which must be borne by the prepared sizes of coal."

### Inelastic Scale Limits Work

"The operators are not opposed to unionism and they expect to continue to deal with the miners' union, but they feel bound to point out that refusal to accept a wage reduction does not guarantee daily earnings or annual income at demanded high levels when an ample and adequate fuel supply is readily available elsewhere."

"To insist that a non-competitive wage rate shall be written into the contract simply means greatly reduced work time for those who do have some work time and entire idleness for many others and a constantly growing decrease in production, all of which is much worse than a flat wage reduction, since it affects not only the mine owner and the mine worker but is against the interest of every mining community, of every industry and of every household and other consumer of coal in the entire state."

A similar note was sounded by Herbert Taylor and E. C. Searle, large coal operators in southern Illinois. Walter W. Williams, Benton attorney, appealed to the rank and file of the miners' union to insist on a wage reduction, "so that the mines may resume operation and this community not revert to the deserted farming village it was prior to the discovery of coal here thirty-two years ago."

The other side of the picture is given by George Stanfield, city editor of the *Herrin News*, who said that conditions are not as bad as they appear on the surface and that if the mines resume operation the community will soon be on its feet. Albert J. Nason, of Chicago, is sinking two shafts and investing heavily in a new mine in neighboring Jefferson County.

There was general disappointment when it became known that the union

side would not be presented. State Senator William J. Sneed, president of the Herrin subdistrict of the United Mine Workers and reported to be a contender for the presidency of the Illinois district of the union in the December elections, had been scheduled to give the miners' side.

In a letter to County Judge Morgan, who had charge of the conference, Mr. Sneed explained his absence as a protest against discussion of wage matters. He said it was his understanding that the conference would seek a remedy for the freight-rate problem as affecting west Kentucky and southern Illinois and that the conferees would unite to ask the Interstate Commerce Commission to eliminate the additional rate contemplated by them for southern Illinois coal.

Union officialdom attributes the present depression to the freight rate on coal and it has enlisted the Illinois Commerce Commission in the fight for a reduction in the rate. John L. Lewis and the officers of the Illinois district have reaffirmed their unwillingness to consider any reduction in the wage scale and Senator Sneed took his stand with them.

William Daech, president of the Taylorville subdistrict of the union, who came to the conference but did not participate, said that the union would never accept a cut in wages.

"We know it means unemployment for many miners, but if we took a cut the non-union operators would simply reduce their scale still further and Illinois would once more be idle. We'd rather starve on a high wage scale with irregular work than starve on a lower wage with more work."

### Railroad Men Tell of Work

Conrad Spens, vice-president of the Chicago, Burlington & Quincy R.R., and B. J. Rowe, traffic manager of the Illinois Central, described the efforts of their companies to serve the Illinois coal fields, but asserted that competition from non-union coal fields was due to lower cost of production at the mine rather than to freight rates, which they said could not be lowered with justice.

Meantime 35,000 miners are without any work and the other 55,000 miners do not work more than half of the time and twenty-six mines have been abandoned and 112 closed indefinitely.

## 20,000 Belgian Coal Miners Strike Against Wage Cut

Twenty thousand of the 36,000 Belgian coal miners in the Mons basin went on strike Aug. 14, declining to accept a wage reduction of 10 per cent. As a consequence a crisis threatens the nation's coal industry. The operators fear they cannot compete with German coal, of which 442,000 tons was imported last month. The fall in the pound sterling also favors British coal. The Belgian coal stocks are large and the operators declare the wage reduction is inevitable.

The Navy Department has called for bids on 8,000 tons of run-of-mine coal for delivery at South Brooklyn. The bids are to be opened Aug. 29.

## Problems In Underground Management

### This Rock-Dust Barrier Fits Odd Places

No Need for a Cabinet Maker to Make a Trough That Will Dump Dust on the Pioneering Explosion and Will Dump Again When the More Violent Blast Comes

THE JOB of making rock-dust barriers has seemed a delicate and rule-bound task to many coal-mining men. They have figured that troughs had to conform exactly to certain specifications and that the attachments were difficult to design. Not so at Rock Springs No. 4 mine, of the Union Pacific Coal Co. There they are making and installing the "Daniels Dust Barrier" easily and without purchasing anything. Elijah Daniels, assistant foreman, worked out the idea, with the aid of a few boards, a two-by-four and a couple of rods threaded at one end.

#### SIMPLICITY AND ADAPTABILITY

This trough is made of two 8-in. light planks nailed together in the customary V-shape with triangular end pieces. The whole is then mounted on the broad side of a two by four, the ends of which extend out 8 or 10 in. These ends are split down so as to be of triangular cross section with a flat base. This base rests in a stirrup which is made of a piece of  $\frac{1}{2}$ -in. rod bent into a 3x4-in. loop at one end and threaded at the other end so that it can be screwed into wooden plugs driven into the roof of an entry.

The 3x4-in. loop and the shape of the end of the trough base permits the trough to turn through 45 deg. This is calculated to dump only a part of the rock-dust contents so that the balance

will be ready to be thrown into suspension by the recoil shock which almost always follows an explosion.

The superiority of this trough over some types is that it is supported strongly by the two-by-four which runs

#### Model Installation

Elijah Daniels, assistant foreman of No. 4 mine of the Union Pacific Coal Co., Rock Springs, Wyo., who devised this new barrier, showing a few troughs hung on 4x4-in. beams.

its full length. This prevents sagging of the trough under the weight of the dust within it, and thus helps to maintain its sensitiveness of balance and quick response to shock. The width of the trough at its top distributes the weight of the load so that it is easily tipped over as it rests on its 4-in. base in the two stirrups at the ends.

Barriers of any number of troughs can be built with this device and the troughs may be of varying length so that the barrier can be fitted into almost any shape of entry. They need

not all be hung in the same horizontal plane, thus eliminating the roof brushing which is ordinarily necessary to make the roof conform to the level of the barrier. Of course some brushing is necessary where entry head room is insufficient but for no other reason.

In the installations already made in Rock Springs No. 4 mine, the troughs are all about 6 ft. long and arranged in staggered order so that, as viewed from either end of the barrier, the full width of the entry is covered. Mr. Daniels

emphasizes the ease with which these troughs can be made and installed. There are no patents on any features of it and no specially designed materials are necessary.

Elaborate dust-tripping devices look well on paper but in the mine they are apt to warp and get out of shape, in which case they may dump prematurely or may not dump when needed. These troughs fit themselves to the mine. They may not look prepossessing to the visitor but they should effectively smother out an explosion.

#### Daniel Dust Barrier

The wooden troughs can be built of any length, but these are 6 ft. long. The staggered arrangement in this installation of the Union Pacific No. 4 mine, Rock Springs, Wyo., permits the full width of the haulageway to be covered. They need not all be hung in the same horizontal plane, so little roof brushing is necessary to make room for them.

# How to Support a Roof, Thus Increasing Extraction and Avoiding Squeezes

A Big Pillar Is Left, Two Rooms Wide, at Six-Room Intervals—Rooms Are Sealed and Big Pillar Extracted From Two Directions

BY CHARLTON DIXON  
Superintendent, Le Noir Coal Co.,  
Indianapolis, Ind.

Many mines in Indiana have had much difficulty and suffered no small loss by reason of squeezes, that develop because the entry and room pillars are inadequate. They come suddenly, burying rails, cars, mining machines and other equipment beneath them. Apparently no method can be devised that will prevent them entirely. A modification of the usual method of

the second from the No. 9 ends. Both rooms are started full width. This provides a protecting block of coal 45x75 ft. in plan.

On the parallel entry the room arrangement is the same except that the blocks are staggered. This places the strongest roof support of one entry opposite the weakest part of the roof on the next. The cost is not increased

and the coal left in place is in such position that it can be recovered easily.

More coal is now being extracted from the rooms by this method than ever before. This is accomplished by thinning down the room or rib pillars to such an extent that they will support the roof adequately, yet offer but little resistance to a general cave. The depth of the bed is from 125 to 150 ft. With heavier cover the two short rooms could be left in the solid as a protection to the entries. When these latter passages have been holed through to a new panel the blocks of coal thus left standing could be attacked near the middle of the panel just completed, part of the coal being taken out one way and part the other. This would provide a rapid extraction.

At the depth mentioned, however, the method above outlined has proved to be both simple and safe, affording ample protection to the entries. The old layout, because of a slight but continuous settlement of the tender roof after a few rooms had been worked out and weight had begun to act on the weak pillars, was extremely dangerous, and roof falls were of daily occurrence. By the new method all this has been eliminated. Freedom from both roof falls and squeezes is now enjoyed even during strikes or long periods of shut down.

**BRASS GAUZES FOR FLAME SAFETY LAMPS**—In most flame safety lamps the gauze has been of iron or steel, states Bulletin 227, recently issued by the Bureau of Mines. Some brass gauzes have been adopted, and a few lamps have been provided with copper gauzes. The laws of several states require that a certain number of lamps must be kept on hand at each mine for emergencies. Lamps used in this kind of service should have a non-corrosive type of gauze as a necessary safeguard. Before bonneted lamps became so widely adopted, iron and steel gauzes had advantages over those of brass. To-day, however, it might be more economical to use a good brass gauze for bonneted lamps used in general service.

## Former Working Method

Every little while the roof would start to move, crushing down the pillars, heaving the bottom and burying rails, cars and mining machines, and making much good coal inaccessible. Such coal even where approached from another direction is difficult to extract being laden by the weight of unsettled roof adjacent to it.

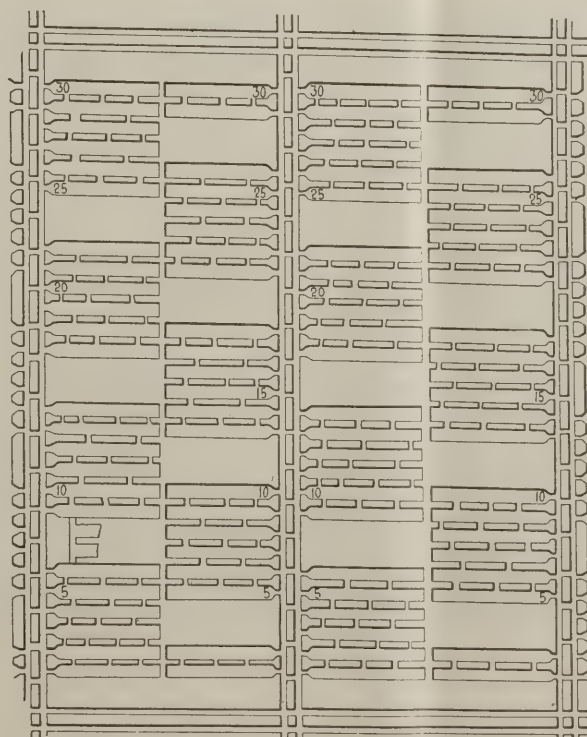

room placement, however, as will be shown, may do much to render operation safer and to save coal that would otherwise be crushed and lost.

About two years ago I took charge of an operation where scarcely a pair of butt entries reached their projected length although none of the room ribs were slabbled. In this region the miners' union insists that tracks be laid in the center of the room. This practice is responsible for the loss of about 30 per cent of the coal in the bed. Under ordinary conditions an extraction of approximately 55 to 60 per cent of the coal is attained. The usual arrangement of rooms is shown in Fig. 1.

In order to prevent the development of squeezes I adopted the extremely simple but efficient method of room placement shown in Fig. 2. Beginning, say, at the lower left-hand corner of the figure, six rooms are successively turned from the entry. Next the distance occupied by two rooms and their rib pillars is left blank. When room No. 6 has been driven 45 ft. (the legal distance) the first crosscut is started. From this, rooms Nos. 7 and 8 are turned, the first from the No. 6 and

## Two Rooms Omitted

These two-room spaces serve as barrier pillars. They prevent squeezes from occurring, and most of the coal in them can be recovered. With this method the pillars can be slabbled. For these reasons the recovery percentage is high. It will be noted that pillars are staggered thus strengthening adjacent ill-supported areas. Illinois and Indiana have both had much trouble from uncontrolled roof despite the low extractions usually attempted.

## Practical Pointers For Electrical And Mechanical Men

### Present Mine Shop Equipment Used For Factory Repair Work

**New Mining Machinery Requires Special Apparatus for Making Repairs—Large Lathe Adapted to Do Horizontal Boring—  
Pump and Motor-Frame Parts Renewed at Low Costs**

SOME coal companies are favorably located near large towns to which they can send their electrical and mechanical equipment to be repaired; others are not so fortunate and therefore must depend upon their own resources when emergencies arise or whenever some special work must be done. In any event certain repair equipment is always necessary at a mine and, of course, the more machinery in the repair shop, the more independent the mine becomes.

Boring machines are nearly always considered an important part of the equipment of a mine repair shop. However, there are few shops equipped with large boring machines. For years there has not been much demand for large machines of this kind among the coal mines but, since the centrifugal pump has been extensively used, mining men have often had occasion to use such a unit to repair centrifugal-pump casings.

Usually a pump casing or mine-locomotive frame is scrapped as soon

as it has worn to such an extent that the parts no longer fit properly. To avoid such losses and obviate the delays occasioned by placing orders for new parts and awaiting deliveries, the Pennsylvania Coal & Coke Co. found that a large boring machine would soon pay for itself. However, before purchasing the unit the workmen looked around for another way to repair their worn pump and motor parts.

In the repair shop of the company located at Gallitzin, a large lathe has been installed for machining heavy pieces of equipment. Locomotive wheels and pump parts are often machined in this lathe.

Turning to the big lathe the workmen soon converted it into a horizontal boring machine. When repairs are to be made to a centrifugal-pump casing or a locomotive motor frame it is set on the lathe and tools mounted on a shaft driven from the face plate do the cutting, the casing or frame being moved to the tool on a traveling carriage specially designed for this work.

**How Repairs Are Made to a Locomotive Motor Frame**

After the worn parts have been built up by welding, the motor frame is accurately mounted on a traveling carriage. The cutting tool is fastened to a revolving shaft driven by the lathe. Inside cuts are made by moving the motor frame to the revolving tool.

### Series Motor with Shorted Interpole Kept in Service

Sometimes an interpole in a direct-current motor burns out or is grounded, thus putting the motor and the equipment it drives out of service until the winding has been replaced or repaired.

In a case of this kind it is possible to operate series motors, especially on

**Cutting Out an Interpole**

By placing a jumper to carry the current around a defective interpole field coil, a motor may be kept in service the remainder of a working day.

locomotives, by simply connecting a strap or jumper across the defective or removed pole to the remaining adjacent poles, which are still in good condition. No change will be made to the polarity of the remaining poles, it being necessary only to take the defective pole out of service. The above method will lead the current across the removed pole and will cause a slight sparking on the commutator, but it will not prove serious to the operation of the motor under light loads. Motors in this condition should not be run under overload. Of course the defective field should be repaired and placed in position as soon as possible.

R. J. HERMANN.

Terre Haute, Ind.

### Pulling Cables into Manholes

Several clever arrangements for pulling electric cables are shown in the accompanying illustrations. One of these sketches shows how special shoring of a heavy beam holding a pulley may be installed. The other illustration shows how a hook may be used. It is obvious that the hook and arm should be long enough so that the pulley will line up somewhere near the center of the conduit.

The necessary pulling power at the

Ways to Pull Cables Through Conduits

Special shoring inside the hole or an iron hook with a pulley may easily be arranged to take the strain of the pulling rope.

mine may easily be obtained from a hoist or locomotive. Special gasoline engines or storage-battery driven de-

vices are also available for this purpose where the hoist must be portable or used without tracks.

Unique Steel Structure

This tower at Donk Bros. mine, Edwardsville, Ill., serves as a guide for the hoisting ropes and an unloading structure. It is fitted with a large crane.

### Rotary Breaks Down Due to Imperfect Foundation

Some few days ago one of the rotary converters operated by our company was reported to be sparking slightly. The attendant noticed that this sparking had gradually increased in severity during a period of about a month.

During heavy loads the brushes on the alternating-current end of the armature threw off fine white sparks, but when the load was low the fire from the rings and brushes practically stopped. After resetting the brushes and polishing the rings the conditions improved but little. The cause of this trouble was a mystery to the attendant.

The other day the armature in this machine burned up. Undoubtedly the sparking at the brushes was a premonitory sign of this accident. Inspection of the damaged machine disclosed no further clew and a spare armature

was installed. As soon as the machine was started it vibrated severely; further investigation revealed the fact that the foundation was loose from the floor of the building.

The cause of the accident no doubt was the vibration of the machine and foundation. Years ago when the rotary was new and the foundation was solid to the floor of the station there was little vibration, but, as years have gone by, parts of the machine are now slightly out of balance and the foundation has proved to be too small.

Little warnings like that given by the sparks at the brushes usually presage trouble, but the cause frequently is ascertained too late.

GEO. MYRICK, JR.

### Tarnish-Resisting Coat for Polished Metal Surfaces

About coal-mine offices, power plants, substations and similar places are frequently many metal surfaces that for the sake of appearance should be kept bright and clean. "Polishing, the bright work" of engines, turbines, boilers and the like is a never-ending job and one that is the bane of the engine tender's existence.

One method of partially avoiding this difficulty consists of polishing the surface that it is desired to keep bright, thoroughly removing all traces of the polishing compound, and then lacquering. Lacquer, however, fre-

quently dulls the luster or bright appearance of the surface upon which it is placed. This is probably due to the fact that to a certain extent it darkens with age.

Another protective coating that may be applied to polished metal surfaces is one of collodion. This dries quickly and is practically transparent. For best results two coats should be applied.

### Holding Feeder Wire from Mine Hanger

Many types of insulators and insulator supports are used in the mines; some are good and some are bad. One of the best types of insulators is the trolley hanger. This device performs its functions under most unfavorable conditions. Often it is mounted on a loose board or a wet roof where the vibration of the trolley wire and the pounding of the trolley wheels combine to cause rust or failure.

In a section of one of our mines, the electrician had been having much trouble with the continued tearing down of the feeder wires, mounted on the side of the gangway. These feeders had been rehung and repaired until most of them were almost bare. This condition made the haulway dangerous, but had new feeders been provided the difficulty would not have been met, for they soon would have been in as bad condition as the old ones. It so happened that an old trolley wire on the side of the road was also used as a feeder. This wire was small and therefore insufficient in itself to carry the total load.

Continual trouble with the feeders on the side of the haulway prompted the electrician to make a change. Looking around he came to the conclusion that the feeders would be much safer and freer from damage if mounted on the roof. The old trolley wire, just mentioned, was mounted on the usual type of mine hangers and after removing the wire and trolley ears the electrician fastened some sister hooks to the hangers as shown in the illustrations. After this was done a heavy feeder was hung on the hooks as shown. The results were unusually satisfactory because no new insulators had to be installed.

As shown in the illustration the hook is turned so that the wire enters between the two prongs. When this is done the hook is turned 90 deg. and the wire dropped into position. The wire is thus locked in place and side strain in any direction cannot pull it out of the hook.

Use of Mine Hanger to Hold Feeder Wire

A, shows an end view with the cable raised in position between the two prongs. B, illustrates a side view of the hook and wire. C, shows the sister hook turned and the wire dropped into position where it is held by the two prongs.

## Discussion

### Saving Time in Gathering Mine Cars

Description of Work of Reel-and-Trolley Locomotive Gathering to Main-Line Locomotive, with Switches for Loads in Inbye Crosscut

BY ALEXANDER BENNETT  
Edwardsville, Ill.

The plan, submitted by Mr. Shacikoski for speeding haulage, in the Aug. 7 issue of *Coal Age*, page 196, is certainly an improvement over the first one mentioned by him, and which he justly criticises as inadequate. Even his remedial method, however, leaves much to be desired, especially where a large tonnage is in prospect. He does not indicate the tonnage obtainable by his revised mine layout and whether it is applicable to a mine that is subject to the generation of dangerous quantities of methane.

My experience has laid wholly in the production of coal where gas is emitted in sufficient quantities to command a wholesome respect. However practicable either of the plans mentioned by Mr. Shacikoski may be in a non-gaseous operation, I am satisfied that neither would be tolerated in any well-regulated gaseous coal mine. This would be particularly true if gas is generated in dangerous quantity, and each panel is sealed off by double concrete walls as soon as the coal is extracted.

I have in mind a mine in which coal is being gathered from the faces, without serious loss of time to either loader or operator. A three-ton car is being used on grades so steep that it is considered to make the use of mules inadvisable, but over which a five-ton reel-and-trolley locomotive can be utilized successfully.

One such locomotive can supply cars to the loaders working after two cutting machines. This, with fourteen men to

each machine, would give an average daily output of 150 tons. The conditions are favorable, with from 6 to 6½ ft. of coal after leaving one foot of top coal in place to protect the roof. The panel system of mining has been adopted.

The accompanying sketch illustrates the method of gathering the coal. Briefly, it is as follows: The haulage locomotive leaves fourteen empty cars on the parting, taking an equal number of loads to the bottom. The gathering motor takes the fourteen empties to the point A, where half of the trip is uncoupled and left. With the other half the gathering machine proceeds to the 1st North and, pushes the cars ahead of it, one empty being dropped into the neck of each room where loaders are working. This is all done in one operation.

The last empty is pushed into the last room to the switch nearest the face. Here the motor couples onto the load and takes it to the entry and up to the next room switch where it is uncoupled. The locomotive then pushes the next empty into the room, up to the switch nearest the face, brings out another load, couples onto the one on the entry, and continues the operation until all seven loads are picked up. These are then pulled out to the point B, at the main-line switch, and left there.

Running light the locomotive then goes to the point A, picks up the other seven empties, backs them into the 1st South, and repeats the same sequence

of operations as in the 1st North but this time leaving the loads at point C. The haulage motor can then pick up both these short trips after its own empties have been thrown in the clear.

With a favorable grade, however, the gathering motor can put all the loads on the parting and save time in switching later on. Each room should be equipped with a latch switch, with heavy latches. The trip-rider should kick this switch open as soon as the loads pass out over it, in those rooms, where loaders are working.

It is necessary to work only one north, and one south entry at a time. In level workings, however, two other machines can operate inside the parting, and the haulage locomotive can pull twenty-eight empties instead of only half this number.

Every successful operation presupposes that those employed shall be "live wires." The plan above outlined is no exception to this rule. The trip-rider and motorman must have average intelligence, and to a reasonable degree must possess the ability to co-operate. They must be predisposed to get maximum results. Where cars are plentiful, doubleheader trips will give still more gratifying results than are attainable by the plan just outlined.

Transportation is today a vital problem in successful coal mining. The sporting instinct, if possible, should be aroused in everyone responsible for the movement of coal toward the shaft bottom. Turn-boards should be placed on each parting where two or more drivers or motormen leave their trips. These should be kept by the trapper or parting tender. Tact and common-sense will do the rest.

### Not Protecting the Fan Duly

In some recent explosions to which reference has been made in *Coal Age* the fan has been put out of commission, thus delaying rescue work. This makes me wonder whether the practice of placing a relief section on the fan way at the surface is in common use. The fan should be at least 50 ft. from the tunnel and the airway leading to it should be of concrete with a concrete roof, but on the way should be a slight turn if the entrance is by a slope or drift, and the outer angle should embody a wood frame made of light dressed lumber that could be made airtight by placing red lead at the joints. A good coating of paint would preserve the wood.

As the frame is at the outer side at the angle the force of an explosion would be directed at it and the fan saved. In the case of a shaft almost a right angle is made in the airway between the fan and the airshaft, and in this case the wooden framework can be put immediately over the top of the shaft. This opportunity for relieving the pressure could not fail to assist greatly in preventing injury to the fan.

The frame could be readily repaired and the ventilation restored in a few minutes after the arrival of help, especially if the right materials were left on the ground and in proper condition for their replacement.

JAMES GRAY.

Newcastle, Wash.

### Haulage Layout

By gathering with a locomotive specially engaged in that service delays are avoided and loaders are kept busy, all this without spoiling the ventilation by excessive interconnection. The use of switches in the last crosscut of each room involves some labor and reduces, in a degree, the efficiency of the arrangements. At this particular mine cars have to be delivered to the working face.

# Production And the Market

## Bituminous-Coal Business Begins to Show Signs of General Improvement; Price Gain Holds

Signs of improvement in the bituminous-coal trade are beginning to appear in most of the market centers of the country, apparently reflecting the beginning of the long looked-for beginning of a fall revival in business. This is the most encouraging development in the industry since the recent prolonged depression set in, the betterment being so much broader in character than the previous fitful flurries as to be indicative of lasting qualities. New England, however, continues to be an exception to the tendency toward betterment. Officials of the Pennsylvania R.R. have issued "shop early" advice to coal consumers desiring to be prepared for the cold weather, warning them that shipments are below normal for this time and that consequently there is a likelihood of a car shortage, with the usual attendant evils, unless there be an increase in movement soon. The New York Commissioner of Markets has expressed himself in a similar vein.

### Dawes Plan Holds Hope for Export Trade

A revival in world trade is forecast by the U. S. Department of Commerce as a result of the adoption by the London conference of the Dawes report, which is hailed as "the greatest effort since the war to bring about economic reorganization in Europe," forecasting a stimulation in exports of American raw materials and the eventual restoration of world markets upon which American producers depend. All of which has an interesting bearing upon the much talked-of plan to build up America's export coal trade.

Coal Age Index of spot prices of bituminous coal continued to maintain the slight advance reported last week, standing on Aug. 25 at 165, the corresponding price being \$2, the same as for the preceding week.

Activities at Hampton Roads showed a pronounced falling off during the week ended Aug. 21, dumpings of coal for all accounts totaling 315,540 net tons, a decrease of 80,028 tons from the previous week.

A further upturn marked the movement of coal at the lakes, dumpings during the week ended Aug. 24, according to the Ore & Coal Exchange, being as follows: For cargo, 804,133 net tons; for fuel, 42,021 net tons. This compares with 765,872 and 42,785 net tons respectively for the week before.

Production of bituminous coal again increased slightly during the week ended Aug. 16, the output, according to the Geological Survey, totaling 7,831,000 net tons. This compares with an output of 7,789,000 net tons during the week ended Aug. 9, according to revised figures. Anthracite production, however,

showed a marked falling off, 1,386,000 net tons having been produced during the week ended Aug. 16, compared with 1,664,000 net tons during the preceding week.

Anthracite also showed slight indications of an early upturn, though tangible evidence in the shape of actual orders is still rather meager. Stove coal continues to be the size most in demand, activity being largely confined to independent coals, which for the most part are quoted below company schedule. The larger companies are still working on a schedule of four days a week, but they all expect to be working full time during September.

### Hopes Being Realized in Midwest

The Chicago coal market is beginning to reflect signs of returning industrial activity and prosperity. The country trade in Iowa, Illinois, Minnesota and the two Dakotas is showing signs of renewed activity and it is expected that their inquiries and orders will increase daily from now on. Smokeless coals in the prepared sizes showed a very slight decrease this week, but eastern Kentucky block coal shows very material signs of strengthening. The market on steam coals is in fair shape. The demand has increased a little but the supply remains just about the same as it was about a week ago. There has been a little strengthening in prices on high-grade screenings in southern Illinois. Operators who have coal loaded on track and can furnish car numbers to the big industrials in Chicago are having no difficulty whatever in disposing of their coal.

### Autumn Buying Movement in Kentucky

Sentiment in Louisville is better, indicating better working time at the mines, freer movement of coal and that many mines that have been operating only half time or less are now running fairly close to full time. There has been a notable improvement in demand for prepared sizes,

while prices are stiffening somewhat on prepared, especially block sizes, and screenings are holding their own in eastern Kentucky and increasing a little in western Kentucky, there being good demand in the latter field and better mining conditions.

In eastern Kentucky it is said that there is little block coal to be had at under \$2.40 to the trade, and more operators are asking as high as \$2.75 for top grades. It appears as if the long-awaited fall demand is at hand and that business will be fairly active over the next several months.

The western Kentucky market has been firmer over the past two weeks, but prices may drop soon if the operators resume operations on a non-union basis at the 1917 scale, as it is also asserted that miners will be paid on a production basis of prepared that will run over a 1½-in. screen, in an effort to force miners to quit blowing coal to dust by overshooting it.

### Northwest Markets Getting Stronger

The Duluth market is stronger with slight increases in prices. Anthracite remains the same as last reported, but the demand is increasing, as the last regular 10c. monthly advance goes into effect Sept. 1. Forty cargoes arrived

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	Aug. 25	Aug. 18	Aug. 11	Aug. 27
Index .....	165	165	163	202
Weighted average price.....	\$2.00	\$2.00	\$1.98	\$2.44

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1924, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

last week, of which nine were hard coal, and thirteen are en route, of which three are hard coal. The railroads are giving good dispatch from the docks and unless ordering falls off considerably the docks will not get choked to any marked degree this year. The second cargo of Ford coal has arrived, being 13,000 tons on the steamer Ford 2nd. Announcement has been made that Ford will bring up 200,000 tons this year.

The requirements of the Northern States Power Co. have just been filled, and 200,000 tons of screenings came to the docks here. This was divided among the Pittsburgh Coal Co., the Peter Reiss Coal Co., the Inland Coal Co. and the Berwind Fuel Co. The price was not disclosed.

There has been some pickup in the Twin Cities of late, but it is a good month late, so that deliveries are far below normal for this time. Prices on dock coal remain at recent levels. Southern Illinois coal is on a \$3 basis as before, with little moving to the Northwest as yet. Hard coal is moving to the interior and to some extent to the Twin Cities, but not as much as normal at this date. Yet the crop movement is under way and that should give a return cargo of coal for the cars which bring wheat and other grains to the terminals.

The Milwaukee market is very quiet. A change in the price of anthracite is promised for Sept. 1, when undoubtedly there will be a greater demand than for some time past. Receipts by lake are slow. Thus far this season 445,323 tons of anthracite and 1,139,655 tons of soft coal have been received. Last season up to the same time 552,680 tons of anthracite and 1,735,700 tons of soft coal had been received.

Western Markets Looking Up

A slight improvement in noticeable in the Southwestern market over last week, the operators believing the fall demand actually has started at last. Increased inquiries more than a month ago were thought to presage the opening of the fall market, but there was a setback in the latter part of July and the first half of August, from which the district only now is beginning to recover. Prices hold at recent levels.

The Colorado market continues to drag along, but it is thought that with the heavy movement of crops the railroads will be demanding more coal and a heavy demand for domestic coal is anticipated, as stocks are reported to be low at nearly all points. Colorado mines worked on an average of nineteen hours last week, 50 per cent of the working time lost being due to no market. Prices remain unchanged.

Utah operators have announced a 50c. increase on sizes above 3-in. nut, this size having been reduced 25c. The new schedule will be as follows: Big lump, \$4.50; 3-in. lump, \$4.25; 3x8-in. lump, \$4; 3-in. nut, \$3.25. Run of mine, screen slack and straight slack remain at \$3.50, \$2 and \$1.50 respectively. Lump coal is moving best now, but there is a demand for all sizes. The domestic storage business is better than a year ago, due, it is thought, to the rising market more than anything else. Industrial buying is light.

Ohio Trade Gains in Momentum

Business at Cincinnati shows a gain in momentum with some slight advances in the quotations of southeastern Kentucky firms, and from Elkhorn mines in particular. The smokeless market is not enjoying as good a position as the bituminous, the cause seemingly being the fact that the steady run of business through the summer has kept the yards stocked on the domestic and the lake buyers are still chary about rushing in for any more tonnage. River business remains at the same volume as for weeks past. The attempt to work through Kanawha coals has been a bit disheartening to those who reopened on an open-shop basis.

With domestic trade showing slightly more activity, there has been a slight improvement in demand in Columbus. Pocahontas and other smokeless varieties are selling fairly well and there is also a good demand for splints and Kentucky grades. There is little doing in steam coal and the trade is marking time, so to speak. Reserves are still fairly large in some localities and buying is mostly for immediate needs. While there is not nearly as much demurrage coal on the market as formerly, still cheap cargoes can be picked up and bargain hunters are busy. Utilities and railroads are good consumers. Schools are taking in a good tonnage while there is also considerable activity in coal for municipal departments, hospitals and public institutions. Production is showing slight signs of improvement. The lake trade is not as active as formerly owing to the fact that the wants of the upper lake region are close to being filled.

Trade in eastern Ohio seems to be moving along with a casual but slightly increasing steadiness. Inquiries show more life, especially in the retail trade, and this demand is, no doubt, emanating from apartment houses, schools and the domestic consumer. Steam stocks are now a negligible quantity, and steam buyers are taking advantage of every opportunity to purchase small lots at advantageous prices, thereby augmenting whatever small stock they may have and at the same time providing for current requirements.

Coal Moving Better at Pittsburgh

Pittsburgh district coal has been moving a little better of late. Quotations on Pittsburgh steam and gas coals have not been favorably affected by the heavier call for coal. The movement of domestic coal is still in the incipient stage, there being nothing like a regular tonnage. Buying demand for slack has increased noticeably. The additional quantity is furnished by strip mines producing somewhat more and by there being more from deep mines, partly through increased shipments of domestic lump. Pittsburgh steam mine-run continues quotable at \$1.75@\$2 as the full range of the market, and there has been no distinct change since the decline to this level late in March.

With little or no change in prices, inquiries are becoming

more plentiful in central Pennsylvania, and although to date not much coal is being sold or contracted for, indications point to heavier buying after Sept. 1.

Demand at Buffalo is about as before, but the feeling is somewhat better. Prices are at the bottom and have not changed to any visible extent for quite a long while: \$2.25 @ \$2.50 for Youghiogheny gas lump, \$2 @ \$2.25 for Pittsburgh and No. 8 steam lump, \$1.75 @ \$2 for all mine run, \$1.10 @ \$1.25 for slack.

### New England Sees Further Price Drop

In New England pool 1 New River and Pocahontas declined 15c. to \$5.25 per gross ton on cars, Boston, brought about entirely by competition, for prices for spot tonnage at the southern loading piers have been slightly firmer. Some business has been done in small lots at \$5.40. Consumers' stocks are larger than has been generally believed. In the aggregate quite a fair tonnage has been booked at the low figure, but it is not as large as was anticipated.

The price seems to be sustained at Providence as no really pool 1 mine-run coal is known to be offering under \$5.40 on cars, with some business noted at \$5.45 within the past few days. And orders are no more plentiful than at Boston.

The situation at the southern loading ports is just a bit firmer. There is little strictly pool 1 mine-run coal offering under \$4.10 gross ton, f.o.b. Hampton Roads, now and 5c. and 10c. more is being paid. Some tonnage of pool 1 coal has been shipped to New England in the past fortnight for which the f.o.b. price was under \$4, but this is no longer possible. Tonnage appears to remain rather heavy, but there is less slack standing and this injects a firmer tone to prices.

The all-rail situation offers nothing new. Regular consumers of Pennsylvania coal are taking it right along, but there is practically no spot buying. Prices manifest no change from the past week or so.
